It is especially important to note that "modernity always had something to do with technology …, and thus eventually with progress" (Jameson, 2002: p. 7). The scientific revolution of the seventeenth century and technological advances led to the transformation of community members in the citizens' 'imagined community' of the nation-state. Distinctive features of modernity are: within the political sphere – a democratic, constitutional state; within the sphere of nation-building – a transition to a national government; within the spheres of science and education – a formation of autonomous studies; and within the economic sphere – a transition to capitalism. The universal packaging of modernizing transformations, characteristic of the twentieth century, operates in several spheres: at the level of a socioculturally organized society, modernization manifests itself in the form of a movement from industrialism to postindustrialism in the economic sphere; in a movement from an authoritarian to a democratic regime in the political sphere; and in the legal sphere as a transition from a conventional to a legal right. Changes in the sphere of religion are of particular significance: modernity is considered to have came into being because people had taken the world out of God's hands, as it were, while still providing possible manifestations of enchantment in the form of contingent meaning.

In accordance with the definition given by the famous English expert in the field of modernization transformation, V. Moore, modernization is "a total transformation of the traditional premodern society into a social organization, which is characteristic of the 'advanced,' economically prosperous and political stable nations of the West" (Moore, 1963: p. 89). However, professor of sociology at the University of Munich, Ulrich Beck, believes that "modernization leads not only to the formation of a centralized government, to the concentration of capital and more subtly interweaving of the division of labor and market relations, to mobility, mass consumption and so on, but also – and here we come to a generalized model – to a triple 'customization': freedom from historically imparted social forms and relationships in the traditional sense of circumstances of domination and liberation ('aspect of freedom'), a loss of traditional stability in terms of effective knowledge, faith and accepted norms ('aspect of demagnification') and – which somewhat inverts the concept of this understanding – to a new kind of sociocultural integration ('aspect of control and reintegration')" (Beck, 1998).

2. The second meaning of modernization denotes the various processes of development of lesser developed catching up to developed countries. Modernization is thus seen as a response to the calls of Western civilization modernity, to which every society gives an answer in accordance with the principles, structures, and symbols laid down as a result of its historical development. In this sense, the term 'modernization' refers to the underdeveloped societies and the description of their efforts in order to catch up with the leading, more developed countries, which coexist with them in the same historical time. In this case, the concept of 'modernization' describes the movement from the periphery to the center of modern society. The theories of modernization, neomodernization, and convergence operate within the term 'modernization' in this narrow sense. Many theorists wrote about the differences and interactions within the premodern (preindustrial) and modern societies in the nineteenth century (Tönnies, 1887; Spencer, 1873; Durkheim, 1893; Comte, 1853).
3. Finally, in the third meaning, modernization is understood as a process of innovative transformations of the most developed countries of Europe and North America, which first began the process of modernization and have long since been deeply rooted in modernity. For example, renowned Israeli sociologist Eisenstadt believes that "historical modernization is a process of change leading to two types of social, economic and political systems that have developed in western Europe and North America between the XVII and XIX centuries and has spread to other countries and continents" (Eisenstadt, 1978). There is also a large body of work on the subject of the transition to a postindustrial society (Galbraith, 1958; Inglehart, 1977; Thurow, 1980; Fukuymama, 1992; Handy, 1993; Bell and Inozemtseva, 2007).

The History of the Study of Modernization

Modernization as a sociocultural macroprocess has its own theoretical foundation – the modernization theory, the formation of which was influenced by evolutionism, functionalism, and diffusionism. Fundamental contributions to the formation of scientific concepts explaining the macroprocess of modernization, i.e., the transition from traditional to modern society (Comte, 1853; Spencer, 1873; Weber, 1905; Durkheim, 1893; Tönnies, 1887; Cooley, 1918; Maine, 1861).

The theories of modernization in their classical form received scientific and public recognition in the 1950s and mid-1960s, when the work of the following authors became widely known (Smelser, 1956; Lerner, 1958; Rostow, 1960; Parsons and White, 1961; Hagen, 1963; Apter, 1965; Levy, 1966; Berger, 1967; Eisenstadt, 1978).

Within the work of functionalists, it is worthwhile to mention the work in classic American and global sociology by Talcott Parsons, who examined the processes of segregation in imported sociocultural experiences in countries that were in the process of modernizing (1961). Parsons believes that in the constant attempts to divide importable, foreign culture experiences into acceptable and not acceptable, a tendency to preserve cultural values "of the highest level is displayed, while concurrently opening the road of radical changes at the next level of value specifications, i.e., on the level of major functional subsystems" (Parsons and White, 1961: p. 662).

We know that cultural anthropology came from studying traditional, archaic forms of human coexistence; this is seen in the works of classical cultural anthropologists (Herskovits, 1940; White, 1949; Kroenbar, 1952). In cultural anthropology, the evolution of traditional, local cultures is seen in two main forms: (1) As a linear stadial evolution of a progressive nature from relatively simple societies to more complex ones. This understanding correlates to the classical understanding of the modernization process. These views are more or less shared in England (Tylor, 1870; Spencer, 1873; McLennan, 1869; Lubbock, 1870; Frazer, 1935), Germany (Bastian, 1860;

Lipset, 1960), France (Letourneau, 1894), and the US (Morgan, 1877). (2) As a multilinear development of different types of cultures. In the latter case, a greater emphasis is placed on the uniqueness of the modernization process and the various kinds of modernity that subsequently arise. Modernization is thus viewed more as the implementation of various historically conditioned types.

Evolutionists, primarily Herbert Spencer (1820–1903), an English philosopher, biologist, psychologist, and sociologist, focused their theoretical constructions on analyzing how societies develop. Spencer outlined his views on the evolution of society in-depth in his fundamental work *Principles of Sociology* (1896). He and his followers paid close attention to progressive social changes, positive outcomes of the evolutionary nature of the modernization processes. They believed that modernizing transformations were unilinear, with lesser developed countries having to go through the same path that developed countries of modernity had already passed; the changes are gradual, cumulative, and peaceful. They stressed the importance of endogenous, immanent causes and described the driving force of the changing terms 'structural' and 'functional differentiation,' 'adaptive perfection' and similar evolutionary concepts. Piotr Sztompka, professor at the Jagiellonian University in Krakow, notes that from the standpoint of evolutionists – supporters of the modernization theory – it was supposed to bring universal improvement in social life and the human condition (1993). Modernization and convergence were seen as necessary, irreversible, endogenous, and beneficial processes. The path of modernizing transformation consists of successive stage segments, such as 'traditional–transitional–contemporary,' traditional – the stage of achieving preconditions for the beginning of change – the beginning of continuous growth – maturation – attainment of the level of mass consumption (Rostow, 1960).

As a result of the development process of modernization, modern became the crowning point of expressing progressivist cultural–civilizational paradigm. The ideology of progress, while becoming increasingly secular, defined the eurocentrism of the historical process throughout the period of modernity, which was indicative of various nations ascending the ladder to rationalism, secularism, and econocentrism. In a generalized form of presenting the views of classic sociopolitical thoughts on progress, Robert Nisbet said that as a whole, the classical concept can be seen as an idea of the gradual liberation of humanity from fear and ignorance toward a higher level of civilization (1980). A stadial approach, adopted for a long time till the last decades of the twentieth century by evolutionists, neoevolutionists, Marxits, and positivists, prevailed and, in an indirect form, is common today in Western science, which largely preserves the spirit of Eurocentrism (Harrison and Huntington, 2001).

Diffusionists interpreted the processes of development as predominantly diffusional, rather than endogenous-evolutionary in nature (Ratzel, 1898; Frobenius, 1898; Graebner, 1911). In contrast to the interpretation of modernization as a spontaneous tendency of evolution, which self-develops from the 'bottom,' diffusionists believed that it started and was controlled from 'above' by the intellectual and political elite which aims to pull its countries out of backwardness through planned, purposeful action. Diffusion acts as a mechanism for modernization change. Interaction between the more developed, modernized and the less developed and modernized societies is a crucial factor of modernization. In transforming countries where modernization is a desired goal, they look to the developed countries in the Western civilization. Consequently, modernization is not just a spontaneous development in a progressive direction. In this understanding, modernization presents itself as a straight and preferably precise transfer of foreign cultural norms, values, institutions, models of work, and leisure from countries that are in a reference group of their own. Modernization, therefore, is not a self-supporting, self-progressing process. Rather, it is the transfer of samples, models, and achievements of developed countries into their own.

Modernization of Non-Western Societies

Modernization processes in non-Western societies can be explained using evolutionary and diffusionist theories. Given the interaction of endogenous (evolutionary) and exogenous (diffusionist) components of the modernization process, the following classification can be presented:

Endogenous forms of modernization – a process, deterministic in endogenous sociocultural dynamics. Modernization is complex due to internal causes, self-developing, self-transforming societies. An example of this type of modernization, starting with the New Age, is the development of Western Europe and North America.

The adaptive ('catching up') type of modernization. Practiced in countries not related to the Western pioneers of modernization, beginning as an adaptive response to the accelerating processes of sociocultural dynamics within the Western civilization modernity, passing the scheme of challenge–response. It is divided into two subcategories:

- Modernization as self-Westernization. Initiated with the aim of achieving internal goals, which includes the need to bridge the technological gap with Western civilization's modernity and to preserve government autonomy. In turn, this type of modernization is divided into two subcategories:
  - Defense modernization. Conducted primarily to strengthen the military and political potential of the state, the change of the actual society acting more as a secondary process to technical and technological borrowings. Under this model, strengthening the modernization of the state is the absolute goal and people are simply a means to an end. An example of this is the Russian modernization from Peter I to the end of the Soviet period, excluding the reforms of Alexander II and the sociocultural transformations of the post-Soviet period. R. Bendix believes that only the "first modernized state has a chance to follow its own path autonomously without external pressure. All other nations are influenced by the struggle between avantgarde and rearguard modernization. The threat of military defeat forces struggling countries (Russia, the Ottoman Empire, or Japan) to reform their bureaucracy and army. Such modernization is described as defense modernization"

(Bendix, 1964). This is extensive modernization, i.e., appropriation and assimilation of foreign cultural achievements, borrowing from the results of innovation without acquiring the ability to actually innovate, which cannot be borrowed.
- Liberal modernization. Carried out in order to change society and liberate people, with the perception not only of the technical and technological tools of Western civilization's modernity, but also the processes that led to the creation of this instrument, Western in the perception of its genealogy institutions, norms, values, and models of behaviors. A classic example is the reforms of Alexander II, as well as the modernization processes of Russia and the former socialist countries of Eastern Europe in the (Gavrov and Гавров, 2004).

- Modernization under foreign custody. It presents itself as the transformation of national sociocultural systems, carried out with the direct or indirect participation of the state or any states belonging to Western civilizations of modernity. As a result, geopolitical sovereignty is not saved. In turn, this type of modernization is divided into two subcategories:
  - Modernization in the form of partial responsibility. Carried out in the spirit of colonial and semicolonial policy, with one or more sectors of the economy serving the interests of the colonial metropolis economy, while other sectors do not receive enough momentum to develop. As a rule, modernization of colonies is not considered or formulated as a problem of policy. Development of social and cultural spheres managed by the state is a result of the activities of colonial administration. An example of this is the British colonial rule in India, which resulted in the formation of a Westernized Indian elite, thus beginning the struggle for liberation from colonial dependence.
  - Modernization in the form of systemic involvement, when one or more states initiate and assume full responsibility for the modernization processes on territories under custody. Examples of this are Germany and Japan after World War II.

This classification is conditional; in practice, there is an interweaving of internal and external factors determining the processes of modernization, although the diffusing component dominates in the modernizing process of transforming non-Western societies.

In the 1970s and mid-1980s, the concept of progress, in particular the theory of modernization, was generally subjected to considerable reevaluation. Within the framework of scientific discourse and the public consciousness, it is questioned as a model of an evolutionary arrangement of the world, its modernization, as well as the concept of progress. Critics of the modernization theory pointed to the low efficiency of modernization transformations in the Third World and their partial or complete rejection. It was recognized that a significant variety of nations of modernity is persisting and likely to continue doing so. There is a contradiction between the uniqueness of the West and the fact that it was a model for the rest of the world, and, on the other hand, the specificities of the dynamics of other civilizations were not fully recognized during the time of Marx or Weber when the spread of capitalism and modernization outside of Europe was in the early stages. However, it has become much more evident in the later stages of modernization after World War II (Eisenstadt, 1978).

As a result of the spread of the modernization processes in different regions of the world, it turned out that the process and the results of modernization are influenced by the sociocultural traditions of the recipient countries. Transforming societies change foreign cultural innovations, yielding hybrid designs in which there are residual elements of the imported foreign culture materials and local sociocultural traditions. Authenticity in relation to the initial samples and practical efficiency of hybrid designs are usually not high.

Global Spread of Modernization

The twentieth century saw a global spread of modernization processes and an institutional environment of modernity. Until the second half of the twentieth century, the real superiority of the Western civilization, the geographical area where modernity was born, presided over the world predominantly and wholly. As an alternative project for most of the last century was a socialist project, representing itself (especially in the USSR) as a desperate attempt to achieve the quantitative economic indicators in governments of modernity. Socialist variations of modernization that were practiced during the twentieth century in various countries of the world, especially in the USSR, were (despite all the ideological differences) only one of the branches of the general modernization process, acting as an adaptive reaction of non-Western countries. It is not coincidental that the traditional area of modernity was perceived as a socialist modernization option since it correlated with the collectivist mentality of non-Western countries. As close as socialism is close to the collectivistic Asia, it is just as far from the individualistic Euro-Atlantic civilization, where its chances are vanishingly small. The revolutionary situation developed in Germany and Hungary after the October Revolution in Russia was the result of a defeat in World War I and a consequence mainly of autochthonous development.

The second alternative project, not claiming universality, was the project of National Socialism. It should be remembered that the processes of modernization present a synthesis of the progressive and inverse dynamics, even though when considering it in a sufficiently lengthy diachronic context, it is dominated by progressive dynamic processes. As a dialectical combination of differently oriented dynamic processes, an example of negative adaptive responses to the challenge of Euro-Atlantic civilizations of modernity can be seen as experience of the totalitarian regimes of the twentieth century, including, above all, the experience of Nazi Germany and Stalinist USSR. Using technological achievements of modernity while denying democratic forms of social organization and human rights, is a severe regulation of the creative potential of individuals.

In the second half of the twentieth century, the situation radically changed as Germany, starting with its Western part, was becoming a key element in the construction of European modernism. Other countries of the European continent, including Italy, Spain, later Poland, Hungary, and other former

socialist countries carved their path in this direction, gradually integrating into the Euro-Atlantic civilization of modernity. The rest of humanity, defined in the years after World War II as the 'Third World,' not only failed to offer a universal, alternative project, but also effective, local development options for non-Western states.

Economically and socially successful groups of Asian nations, with modernization processes within the framework of Islamic civilizations, worked toward building an economy while taking into account their activities in religious institutions, such as prohibition of levying interests on loans within the Koranic tradition.

The Western civilization's period of modernization is increasingly developing on a horizontal plane, leaving behind its gradually diminishing vertical dimensions. Note that under the vertical direction, we understand the value of sacral-transcendental dimensions, and under the horizontal dimension – the value of the earth's material life. This departure from the sacral-transcendental nature is seen in the transformation and filling of the new, secular content, Christian in its genealogy. Non-Western civilizations were long unable to answer the call of the Western period of modernization, largely because of the priorities of their civilizations, which are encompassed in the vertical dimension above the horizontal. Within the modernization process, a desire to 'catch up and overtake' the state of modernity without losing or, on a smaller scale, not radically transforming traditional civilizational identities, is seen as problematic.

In the case of a practical implementation of these transformational projects, achievable at the cost of extreme tension of the strength of the society and state, the system with a multivector direction of movement cannot effectively function on any of these planes. Infantilism and mythology of mass consciousness continues today and not just in Russia, with a focus on the possibility of reaching civilizational benefits and a standard of living, yet without any significant sacrifices.

Attempts at modernization in the planar civilizational dimension (which includes the economy, forms of social organization, technology, etc.) while maintaining the primacy of the vertical dimension of civilization (with its spiritual and religious components) is an unattainable utopia. However, the desire to preserve civilizational identity leads to an individualized relationship between the local (civilizational) and the universal (stadial). In turn, this relationship with respect to the local civilization is not static, instead being determined by the intensity experienced by endogenous historical and sociocultural dynamics, adapted by its character in relation to the dynamics of exogeny produced within the framework of the Western civilization period of modernity. The attempt to converge archaic traditionalism using scientific, technical, and organizational achievements of modernity turned out to be unsuccessful and destructive. Modernization in Nazi Germany, Fascist Italy, and the Leninist–Stalinist USSR paradoxically were against modernity in its classic sense.

Militarization, social mobilization, the cultivation of national unity, intolerance of political, ethnic, sexual minorities – all this can be seen as rejection of an important part of the ontological content of modernity – political democracy and human rights, the priority rights of the states, and the nation under human rights – "You are nothing, your people are everything." Such rejection of ontological content of modernity, adopted and overused, engenders technical–technological, bureaucratic, and penitentiary innovations.

Unlike German projects, the Soviet alternative project of modernization and modernity claimed universality, and therefore was international. Going back to the ideological constructions of Karl Marx, in the practice of state building, Marxism was revised by the social and cultural transformations. A Marxist revolution happening in an underdeveloped peasant agrarian country, which is what Russia was at the time, became a challenge to classical Marxism. Soviet modernization became a classic example of defense modernization. This is a complex version of modernization as an attempt to redesign the ontological foundations of modernity, not with the goal of protecting the old providential, but in order to create based on the belief in Communism and the Communist Party.

Today, it can be argued that globalization is a modern stage from which we deploy a single and universal 'project of modernity.' Globalization, manifested in the movement to integrate economic, legal, informational, educational, and ultimately, cultural space, is the current stage of modernization. There is a whole vector stream of modernizing/globalizing changes moving toward an interconnected, mutually supported world that is based on the institutions and values of Western civilization modernity.

Globalization is a large-scale process of disseminating institutional and value-normative environments on a global scale, which leads to greater access of the borders of nations and to a significant weakening of national sovereignty when public functions are transferred to the transnational level. This process is due to various reasons, most notably the emerging reductions of the functions of national governments to functions of local self-government (postal services, part of the system of education, police functions, etc.). The most important of these is the depth of geopolitical sovereignty on its territories; subjected to rethinking, evolution occurs in the direction of reducing the powers of the nation-state. In the period of late modernity, fewer and fewer states can earnestly talk about ensuring national security with the help of armed forces; economic, educational, and fiscal space is increasingly taking on a supranational nature and becoming less controlled at the national level.

In the process of globalization, the identity of modernized people goes beyond national borders, taking on a transnational form of self-identification. This increases the level of freedom, transforming the national community and cultural traditions. Forms of social prestige, referential models of behavior, along with norms and values, are all modeled and translated within a framework of emerging global information and cultural space.

Today, vectors of historical and sociocultural dynamics shifted from institutionalized, vertically integrated forms of social solidarity to network forms (Castells, 1997) and social movements, global and Western in their genealogical norms, values, and models of behavior. People of the age of late modernity can identify themselves with transnational movements, as well as with antiglobalists, environmentalists (e.g., Greenpeace), sexual minorities, youth movements of the nonconformist types, owners of vehicles, washing machines, shampoos, users of certain brands and services, etc. A person can act as an owner of a house built as a specific project, a car of a certain model, make a choice between Pepsi or Coca-

Cola, root for a football team which is often not the team of the person's country, etc. Moreover, new forms of self-identification and solidarity are identifying with the cultural products produced globally by the media. A person can be aware of himself or herself as part of a prestigious social group that is created and reproduced with the help of various forms of advertising.

Today, it can be argued that the large-scale modernization that arose in the civilizational space of Western civilization is similar to the spread of Greek culture in the ancient world. Despite the multiplicity of interpretations of modernization transformation, most of the transformations of the world can be historically compared to the times when the Greek cultural tradition became the basis for common traditions of Roman antiquity. In the new stage of historical development, something similar is happening in relation to modernity, where by means of diffusion, modernization is extended from the Western civilizational arena of modernity.

Modernization as a Communication Phenomenon

Modernization as a macroprocess of transition from traditional society to the society of modernity can be theorized in terms of three discourses, each differently conceptualizing modernization as a communication phenomenon that involves the changing ways of interaction and media use.

The first discourse is a discourse of representation, grounded in the Cartesian legacy and the ideas of positivism. In this view, communication is conceived as a process of the production and transmission of truth claims. From this perspective, modernization is evaluated in terms of its effectiveness and not as a process of democratic participation and decision making. It is from this perspective that many ideas were promoted through mass media that were considered essential to modernization, such as technical innovation, functional differentiation, the power of reason, etc.

Modernization was equated with the transfer of such ideas from a modern, industrialized West, to the less-developed societies. In fact, in 1961, the United Nations declared the decade of the 1960, the Decade of Development. As President Kennedy put it in launching the Decade at the UN in New York, "To those peoples in the huts and villages of half the globe struggling to break the bonds of mass misery, we pledge our best efforts to help them help themselves." The theoretical platform for such efforts was provided in such scholarly publications as David Lerner's *The Passing of Traditional Society* and Wilbur Schramm's *Mass Media and National Development*.

The second discourse – a discourse of interpretivism – is a reaction against the view of modernization as 'the magic bullet' with an explicit or implicit Western bias. The discourse of interpretivism does not see a modern society only in terms of such indicators as its level of media development or GNP, calling to consider other factors such as income disparities, etc. According to this view, mass media are not assumed to be a neutral force; behind all flows of information and goods, one must look for certain ideological forces at play and interpret their influences on the process of modernization. In addition, one cannot have complete faith in new information and communication technologies as a perfectly efficient vehicle of modernization. On the contrary, often developing countries come to be dependent on mass media in the core, modern societies: this is a key thesis of the media dependency theory (Schiller, 1976).

The discourse of interpretivism does not reject the ideals of the Enlightenment; rather, it tries to understand how that modernist vision can be saved and enhanced by opposing the interactionally constituted 'lifeworld' to instrumental rationality. In this respect, attention is shifted from a supposedly disembodied mind to a communication community of real-life people who do not live by representing an already existing reality, but engage with one another in various forms of communicative praxis. The discourse of interpretivism thus is based not on a correspondence, but consensus theory of truth, and the constitutive nature of language (Habermas, 1985a; Gadamer, 1960).

The third discourse is a discourse of reflexivity; it takes the critical thrust of interpretivism a step further by extending the examination of every action to the agent instigating it. As a result, the discourse of reflexivity aims at providing a constructive corrective to the nihilistic danger of deconstruction. No longer understood as a simple relationship between knowledge and control, modernization can only be understood as constant efforts to bind time and space through (self)-reflexivity. According to such theorists as Ulrich Beck and Scott Lash, (self)-reflexivity is crucial because uncertainty is inherent in every communicative action and modernization has a truly global, and potentially destructive, impact (1994). The exact dynamic of modernization, therefore, cannot be predicted and any claims for technological and scientific certainties, or 'final truths,' can only be theorized in the act of self-reflexivity.

In a way, modernization is always 'on the move.' Not surprisingly, more attention is now paid to new social movements with a heightened awareness of the transformative implications of their actions, e.g., democratic, environmental, and peace movements. Also, it is no surprise that calls are made, not only by activists but theorists as well, for new forms of public dialogue that would present the process of modernization in its phenomenological flesh.

What sets the discourse of reflexivity apart, among other things, is the realization that modernity can only gain an access to itself by a series of partial and conflicting descriptions. To put it differently, its ground is constantly slipping from under its feet: "To be modern is to be part of a universe in which, as Marx said, 'all that is solid melts into air'" (Berman, 2010: p. 15). It is due to this inherent dynamic between the original tenets of modernity and its institutional frameworks, within which these tenets can only partially be implemented, that modernization combines self-realization with self-doubt, both revealed in the discourse of reflexivity. And, it is because of this dynamic that modernity cannot but remains 'work in progress.' One can only hope that not only have we always been, but we will always continue to be, modern.

Modes of Production

Donald L Donham, University of California, Davis, CA, USA

Abstract

Marxist social theory is often thought of as 'materialist' and 'determinist.' Just how misleading this characterization can be emerged principally in the 1970s in a wide-ranging conversation about modes of production. This article attempts to summarize the lasting contribution of this intervention by reviewing what modes of production are, how they are structured, and why they change over world history.

Concepts in the social sciences often go through intense phases of development followed by periods in which they take on background status. In the latter times, ideas remain alive, but they are no longer being extended or deepened. One example is Karl Marx's notion of modes of production. First developed in the nineteenth century, the idea of modes of production underwent a dramatic transformation in the late 1960s and 1970s as anthropologists, economists, historians, and philosophers were drawn into a wide-ranging conversation. The critical impulse was largely spent by the 1980s, but by that point, aspects of Marx's thought had been developed in strikingly new directions. Some might even think that Marx had been stood on his head.

This article is an attempt to set out some of the enduring legacies of this discussion. It defines forces and relations of production and describes how the first may be thought to determine the second in the creation of distinctive ways or modes of producing social life. Karl Marx's term *Produktionsweise* is usually translated into English as 'mode of production,' but it might be more simply rendered as 'way of producing.' Never precisely defined in Marx's work – yet arguably at the center of it – *Produktionsweise* refers to both a form or structure and a way of producing. One might say that Marx's object in *Capital* was to show how the first – a particular structure of unequal power and wealth – was both the cause and the result of the second, men, and women pursuing their individual ends within capitalist cultural assumptions.

One notable aspect of the capitalist mode of production is, according to Marx, its inherent instability. Crises are necessary, built-in features of this way of producing; they are not somehow accidents caused by factors outside it. As individuals pursue their capitalist projects, there comes a point, finally, when the entire social system can no longer be reproduced. Then, social revolution appears on the horizon, and the mode of production stands to be fundamentally transformed.

Even though Marx referred at times to other modes of production – primitive communist, the ancient, Asiatic, feudal, socialist, and finally modern communist – his only developed work was on capitalism. On what would come after capitalism, he offered only the vaguest of outlines; it would fall to Lenin and others to construct actually existing socialisms. And on what came 'before,' Marx sometimes reflected only the European prejudices of the nineteenth century. For example, he thought that the Asiatic mode of production was inherently static and would waken to change only through the effects of Western imperialism.

The grand evolutionary teleology in Marx's view of history – the circular but progressive spiral from primitive to modern communism – accounts for much of the political appeal of Marx's ideas. Ironically, that appeal was felt mainly in countries on the periphery of capitalist development such as Russia in 1917, China in 1949, and Ethiopia in 1974; in such locations, the notion of stages of history appeared to offer a road map to a better future, a way to skip ahead to modernity. But this aspect of Marx's work also accounts for its ambivalent reception among social scientists who, even if they identified with progressive politics, distrusted apparent teleologies and grappled with refractory evidence.

As Marxism began to provide the legitimating ideology of socialist states in the twentieth century, it tended to stagnate there. In the capitalist West, however, Marx's ideas received critique and development, principally during periods of crisis. Dogmas of various sorts were questioned, and eventually a more flexible version of Marxist theory took its place alongside others in the social sciences.

In the field of anthropology this began after the upheavals of 1968, particularly in France where, under the influence of structuralist philosopher Louis Althusser, scholars such as Claude Meillassoux, Pierre-Philippe Rey, Maurice Godelier, and Emmanuel Terray attempted to extend the notion of modes of production to so-called precapitalist societies. In this article, I attempt to summarize the lasting legacy of this conversation. I do so, not in the structuralist vocabulary of the time, but in reference to what I regard as the clarifying, later work of British analytical philosopher G.A. Cohen.

What, then, is a mode of production? Perhaps the simplest answer is that it is a model of certain basic regularities that hold across and therefore define historical epochs. At the heart of these regularities is the interrelationship between technology in some broad sense and forms of social inequality. According to Marx, the first (*Produktivkräfte*, or productive forces) determines the second (*Produktionsverhältnisse*, or relations of production). These two constitute the base of a mode of production, which, in turn, determines the superstructure.

Productive Forces

Productive forces are anything that can be used in productive interaction with nature. On this reading, productive forces are not simply raw materials or tools; more inclusively, they are human skills, productive knowledge, and even the technical

 http://dx.doi.org/10.1016/B978-0-08-097086-8.12110-5

aspects of human cooperation in the labor process. These factors Marx considered as equally 'material' in that all can be utilized to produce. But most current readers would probably classify objects, knowledge, and the technical aspects of cooperation as, respectively, material, ideal, and social.

The most striking aspect of productive forces has been their tendency to expand over human history. In the most general sense, the anterior cause of this tendency appears to be located in human nature itself. Humans everywhere develop their powers and skills in a continuous dialectic with nature, and when presented with a choice between more or less efficient means of production, humans everywhere (with certain limited exceptions) choose the first.

If productive forces have tended to expand, this fact can be established only at the world level. Some individual societies have stagnated; some have even experienced local declines in the level of productive powers. As will become clear in this article, relations of production can prevent technical development beyond a certain point. For any particular society in stasis, there is no reason to believe that new social relations compatible with the further expansion of forces must develop. In fact, technical knowledge tends to diffuse from place to place, and typically the most 'advanced' societies are not the ones that give rise to the next development. Rather, peripheral groups that are the recipients of the productive knowledge of their more 'advanced' neighbors often leapfrog ahead.

Just what determines the level of development of productive forces should be considered. A society's mass of productive forces is determined by two factors: the first is the average productivity of labor, and the second is population. The product of these two factors yields the level of productive forces. In this formulation, population itself is not a productive force, yet it enters into the determination of the level of productive powers.

Relations of Production

Relations of production are not, as the English phrase suggests, simply the social relationships formed in the actual process of production. Rather, they are the *de facto* power relationships that both underlie and are the result of the division of the fruits of a society's total labor. Household head versus dependents, chief versus subjects, master versus slaves, feudal lord versus peasants, and capitalist versus workers – relations of production are basic asymmetries of power grounded in the organization of material life. In capitalism, relations of production rest upon actual control over productive forces in the process of production, but in other modes of production, as anthropologists and historians eventually showed, this is not necessarily the case.

In relation to the last point, consider the contrast between capitalism and precolonial chiefdoms in Africa. Capitalists put the production process into motion; they or their representatives oversee and supervise in order to ensure that a profit is produced at the end of the work cycle. In many chiefdoms, chiefs did not control the production process itself. Yet, having produced, subjects brought tribute, the fruits of their own labors, to the chief. This contrast illustrates the fact that relations of production, by definition, correspond to the basic structures of power in a society, however that power is constituted – whether by economic, coercive, or religious means (or some mix of these). This makes the reformed notion of modes of production quite different from what is often assumed of Marxism; most particularly, it is not a form of economic reductionism.

Why do productive inequalities occupy a central place in Marx's thought? The answer is that they locate the basic divisions within any society, the lines of potential opposition – of contradiction. Marx saw these as the potential fault lines along which tensions tend to build up are routinely dissipated by small readjustments, and are sometimes violently resolved by radical realignments. These fault lines are structural; they do not necessarily lead to actual struggle and conflict (indeed, the function of the superstructure is precisely to prevent such occurrences). Nevertheless, contradictions always exist as potentialities; they lie just below the surface.

Forces Determine Relations

Ordinarily, if a factor X is said to determine factor Y, then X is taken to cause Y. Given X, Y is uniquely specified. Transferred to Marx's scheme given here, this understanding of determination yields what has been called 'vulgar Marxism.' Such an interpretation can be supported by some of Marx's own, more incautious summary statements: "The handmill gives you society with the feudal lord; the steam mill society with the industrial capitalist." Empirically, it is clear that the same technology can exist in different modes of production.

A great deal of effort has been expended by commentators to explicate Marx's notion of determination – from examination of dialectics to, in Engels' phrase, determination only 'in the last instance.' Probably the best way to clarify Marx's claims is to note that they are forms of functional, not causal, explanation. Immediately, a distinction needs to be drawn between functional explanations and the theoretical school known as functionalism in sociology and anthropology: Marx used functionalist explanations, but he was not a 'functionalist' in the second sense.

Functional explanations have a distinct logical form in which the effects of a trait enter into the explanation of the presence of that trait: for example, when Y's presence is partly explained by some positive consequence Y has for X. In such a case, X can be said to determine or 'select' Y because of Y's effect on X.

Marx believed that the level of productive forces selects relations of production. For any given level of development of forces, there is only a limited set of relations possible – namely, those that are compatible with and in fact promote the further development of forces. Here, X hardly causes Y in a one-way pattern of determination. Rather, the reverse is closer to the truth: it is Y's effect on X that is paramount. Particular relations cause expansion in the forces. Herein lies the rub, however. As forces expand, they reach a level that is no longer compatible with the existing relations of production. At that point, according to Marx, revolution becomes a possibility. In this way, continuous incremental change (in forces) is mapped onto occasionally discontinuous revolutionary change (in relations) in the base of modes of production.

Bases Determine Superstructures

One of the important contributions of G.A. Cohen was a clarification of the notion of superstructure. If Marx claims that the base or, more precisely, relations of production determine the superstructure, then a definition of relations and superstructure must be found in which the two are clearly distinguished. The difficulty is that power as we find it in any social formation is inevitably encased in particular cultural and legal concepts (i.e., superstructural notions). It was for this reason that Cohen defined relations of production as the *de facto* distribution of power. Every culturally encoded right, he argued, can be matched with a *de facto* power. And it is *de facto* power that determines culturally specific notions, rather than the reverse.

One important effect of this definitional move is to place the long-term dynamic of a mode of production outside of culture itself. Eventually, culture corresponds to *de facto* power rather than the reverse. But in the short term, it places culture at the very center of the analysis of modes of production, for it is precisely the superstructure that defines and stabilizes relations of production. Once again, the logic of functional explanation turns the ordinary expectations about Marxism upside-down. If something is described as having a base and a superstructure, we think of the base as a foundation. It supports the superstructure; without the foundation, the superstructure would fall to the ground. Yet, the logic of functional explanation requires the opposite: it is the superstructure that defines the base.

To adapt a visual image from Cohen (1978), consider the following: Four pieces of wood of the same length are driven a little way into the ground. They stand, but they are easily blown over by a strong wind. A top is attached to the four struts such that the whole becomes a table. The struts, now legs, stand solidly upright. They do not wobble in the wind. Of the tabletop, one can say that (1) it is supported by the legs, and (2) its very existence is required for the legs to be legs. Without the top, the legs would not be legs – only sticks of wood of such-and-such a length. Here, we have a building whose base and superstructure relate in the proper way.

The conclusion to this line of thought (heretical to some Marxists) is that *Capital* is an analysis of the capitalist superstructure – the set of culturally specific and legally encoded meanings and practices that tend to stabilize capitalist relations of production. In a comparative sense, this conclusion is crucial since it sets capitalism on the same analytical plane as any other mode of production. On this view, the analysis of modes of production becomes a matter of locating effective power difference over material production as they are reflected in differential control over the total social product and analyzing the meanings and practices that tend to reproduce such powers – what Antonio Gramsci called hegemonic culture. It goes without saying that it is always misleading to import the cultural logic of one mode of production (such as capitalism) into the understanding of others.

Functional Alternatives

If this reading of Marx's notion of determination solves many conceptual problems, it also creates others in the application of Marx's ideas. Carl Hempel and others have called attention to the difficulties of actually carrying out functional explanations. Not the least of these stem from the problem of functional alternatives. That is, there is often more than one Y (Y_1, Y_2, Y_3, …) that can fulfill any given function. That being so, the particular presence of Y_1, say, cannot be explained simply by referring to its function, for Y_2 or Y_3 could have served the same need.

Figure 1 A possible set of forces and relations of production when functional alternatives exist.

The critical question becomes "What is the size of the set of functional alternatives?" Implicitly, Marx appears to have believed that alternatives are quite limited – typically to the set of one. Consider such a limiting case. For each level of development of productive forces, there is only one set of relations possible. History therefore proceeds in a series of discrete steps from A to B to C. Both the past and the future are specified – socialism is inevitable because it is supposedly the only economic system consistent with highly developed forces.

A different story emerges if the number of functional alternatives is even moderately few. If several different sets of relations of production are compatible with any given level of forces, then the grand design of world history becomes considerably more complex. One possible trajectory in Figure 1, for example, would be A to C to B to D. In this reading, the future looks considerably more open. There may indeed be functional alternatives to socialism – if indeed socialism as we have known it is compatible with developed forces.

Conclusion

The notion of a mode of production is a deliberate simplification. It provides a model of certain central relationships that define epochal forms. As such, the analysis of modes of production cannot substitute for the examination of particular cases in specific spatial and temporal contexts. In this sense, mode-of-production analyses do not constitute historical explanations.

In a larger sense, however, the concept of ways of producing furnishes the necessary scaffolding without which local historical explanation would be impossible. Comparison and contrast, whether explicitly or implicitly carried out, depend upon an overarching framework. This is what Marx's notion of modes of production provides: a way of understanding society and history in the broadest terms.

The present is once again a moment of deep crisis in world capitalism. Accordingly, it would not be surprising if the social sciences produced another efflorescence of Marxist-inspired ideas, but if so, it will unlikely do so in reference to a comparative analysis of modes of production. After the disintegration of the Soviet Union and the elimination of socialism as a world model, nothing remains but capitalism. In 1968, it was possible at least to imagine large parts of the earth as 'noncapitalist,' but now there is, for the first time in human history, one truly globalized world capitalist system. Deepening the analysis of the present will require taking into account what was learned in the 1970s: namely, that capitalism is no more 'economic' than other modes of production and no less dependent upon a series of culturally peculiar ideas. Once the analysis of modes of production is truly leveled in this respect, we will have a more powerful approach to capitalism itself, one that does not naturalize capitalist culture.

Modularity and Organizations

Carliss Y Baldwin, Harvard Business School, Boston, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Modularity describes the degree to which a complex system can be broken apart into subunits (modules) which can be recombined in various ways. Modularity is important for organizations and the economy because the boundaries of organizational units and corporations are likely to match the boundaries of underlying technological modules. (This correspondence is called 'mirroring'.) In this article, I explain the concept of modularity and describe how systems can be modularized. I then explain why mirroring is likely to be a commonly observed organizational pattern, review the empirical evidence, and conclude with open research questions.

Introduction

Modularity is a property of complex systems, both natural and artificial. Loosely speaking, the term describes the degree to which a given system can be broken apart into subunits (modules) which can be assembled and recombined in various ways (Simon, 1962 [1981], 1981; Schilling, 2000 [2003]). There is no universally accepted measure of modularity, however, highly modular systems are made up of many, small, loosely coupled components, while a nonmodular system is a single large structure in which 'everything depends on everything else.'

Modularization is a structured learning and design process aimed at making a complex system more modular (Baldwin and Clark, 2000; MacDuffie, forthcoming). The process was first invented at IBM in the mid-1960s to address looming problems in the design, production, and marketing of early computers. IBM System/360 was the first computer to be designed as a modular system with fully interoperable hardware and software across a wide range of processors. The process of modularization was subsequently refined through applications to software, semiconductor chips, mini and personal computers, and digital communication networks.

Modularity is important for organizations and the economy because the boundaries of organizational units and corporations are likely to match the boundaries of underlying technological and task modules. (This correspondence is called 'mirroring' or the 'mirroring hypothesis'.) As a result, changes in the modular structure of products and processes have the potential to change the structure of industries and disrupt established firms.

In this article, I first describe the development of the concept of modularity, then a series of attempts at modularization and lessons learned from both successes and failures. I will then describe the origins of the mirroring hypothesis, explain why mirroring is a commonly observed pattern in industrial organization, and review the empirical evidence on mirroring. I conclude with a list of open research questions.

The Concept of Modularity

In a 1962 essay on 'The Architecture of Complexity,' the polymath Herbert Simon proposed that complex systems would be organized as hierarchically as a set of inter-related subsystems "until we reach some lowest level of elementary subsystem" (Simon, 1962 [1981, p. 196]). Using the famous fable of two watchmakers, he went on to argue that the organizational structure most favorable to evolution was a 'near-decomposable' hierarchy in which interactions among elements within subsystems were strong, while interactions between subsystems were weak. Two years later, the architect and design theorist Christopher Alexander made a similar observation: "No complex adaptive system will succeed in adapting in a reasonable amount of time unless the adaptation can proceed subsystem by subsystem, each subsystem relatively independent of each other" (Alexander, 1964, p. 41). Both men credited the concept of 'selection by components' to the cybernetics pioneer W. Ross Ashby. The presence of units whose elements are highly connected within the unit and only weakly connected to other units is a defining property of modular systems. The highly connected units are called modules (Baldwin and Clark, 2000).

The concept of modularity was further advanced by the computer scientist David Parnas. Writing about software, he defined a 'module' as a work assignment to an individual or small team and 'modularization' as a set of work assignments for a complex software system. He then proposed that "every module … [should be] characterized by its knowledge of a design decision which it hides from all others. Its interface [should be] chosen to reveal as little as possible about its inner workings" (Parnas, 1972 [2001, p. 151]). Behind this concept of 'information hiding' lies a strategy for minimizing coordination costs across a large group of designers. Each team needs to know a lot – possibly everything – about its own module, but comparatively little about other modules. Thus information about modular systems can be parsed into 'visible' and 'hidden' information. Insofar as changes to the system affected only hidden information, they would be relatively easy to implement, hence the system would be more adaptable. Thus information hiding makes modular systems evolvable.

Karl Ulrich (1995) defined modularity in relation to product architecture. A product architecture is (1) a list of functional requirements; (2) a mapping from functional elements to physical components; and (3) the specification of interfaces among the physical components. A modular

architecture is characterized by a one-to-one mapping of functions to components (i.e., a distinct physical component performs each function) and 'decoupled' interfaces. In contrast to other definitions of modularity, Ulrich's definition rests on a prespecified and stable list of functions, thus it is most often applied in contexts where the conceptual frame of the artifact, i.e., its functions and interactions with users and the environment, are well understood.

Schilling (2000[2003]) emphasized the reconfigurability of modular systems. Modular systems take in heterogeneous inputs and arrive at heterogeneous outputs, thereby satisfying consumer demand for high variety: "[if] all customers want the same thing, there is little to be gained through offering a modular system" (2000[2003, p. 179]).

Baldwin and Clark (2000) defined modular systems as those displaying high levels of decomposability and information hiding, which in turn lead to three economic benefits. First, modularity reduces cognitive complexity, making the overall system easier to understand. Second, different modules of the system can be worked on concurrently and in parallel, reducing time to completion. Third, through information hiding, modular systems accommodate uncertainty: "if new knowledge later yields a better solution for one of the hidden module designs, then it will be relatively simple to incorporate the new solution without changing much in the rest of the system. … [Thus modularity] creates *options* within the design" (p. 91). The authors go on to develop a mathematical model, based on options theory, to value modular systems.

The Process of Modularization

Since the mid-1960s, processes of modularization have been observed in many settings. Some efforts were successful, while others were failures.

In the 1950s, IBM instituted a Standard Modular System for manufacturing transistor circuits. Circuits were constructed on standard-sized cards that were pluggable into a standard box. The system allowed mass production techniques to be applied to the manufacture of complex electronic circuits, thus reducing the cost of the most basic building block of a computer.

Following this success in manufacturing, an IBM task group attacked the twin problems of rationalizing IBM's diverse product line and reducing the cost to customers of upgrading hardware. (At that time, IBM sold six incompatible processors, thus most hardware upgrades entailed rewriting virtually all software applications as well as retraining field personnel.) The result was System/360, which has been called the first modular computer system (Ferguson and Morris, 1993). All System/360 processors were 'binary compatible,' i.e., they could process the same software programs, and the peripheral equipment could be mixed and matched with processors to suit customer needs. Introduced in 1967, System/360 was both a technical accomplishment and a huge economic success (Baldwin and Clark, 2000).

In contrast, attempts to modularize System/360s system software failed utterly. Managers initially divided the system-to-be-built into 40 subprojects and allocated more than 1000 people to the task of delivering the software. But unsuspected conflicts emerged between the code modules and the work fell further and further behind. The experience led Frederick Brooks, a key architect of System/360, to propose 'Brooks Law': "adding people to a late project simply makes it later." He also asserted that system software could not developed in a modular fashion, but required highly coordinated teams controlled by a 'master architect' (Brooks, 1975[1995]).

But Brooks did not make allowances for advances in knowledge about how to build system software. Even as his book was going to print, Ritchie and Thompson at Bell Labs revealed Unix, a new operating system that was modular in both its structure and the way it dynamically managed computer resources in real time (Richie and Thompson, 1974). Unix went on to become the foundational design for many modern operating systems. Together with its descendants, it offered a clear counterexample to Brooks' theories of software development (Raymond, 1999). Indeed, Brooks (1975[1995], p. 271) later admitted that he had failed to appreciate Parnas' 'information hiding' as a basic principle of modular software design.

Subsequently, Mead and Conway (1980) successfully modularized the design of semiconductor chips. However, attempts to modularize the design and production of automobiles largely failed for two reasons: (1) elements related to the same function, e.g., braking, are not collocated, but spread throughout the vehicle; and (2) companies did not invest *ex ante* in learning about critical interdependencies or alternate decompositions (MacDuffie, forthcoming).

Drawing on engineering research documents, especially Mead and Conway (1980), Baldwin and Clark (2000) provide general description of the process of modularization. A nonmodular design, by definition, contains many dependencies between design elements, so that a change in one element will require changes in other elements, which in turn will propagate throughout the entire system. The process of modularization entails the following: first, identifying each dependency and understanding various ways of solving it; then, eliminating the dependency by adopting a 'design rule.' Through systematic repetition of this process, unwanted dependencies across different 'blocks' of the system can be eliminated, while fruitful dependencies within blocks are retained. Eventually, the system arrives at the characteristic modular structure: it will be highly connected within subsystems and independent (except for design rules) across subsystems.

The process can be illustrated with the aid of a design structure matrix (DSM) (Eppinger, 1991). In a DSM, decisions about the design of a complex system are arrayed along the rows and columns of a square matrix. If changing one design decision changes another decision, then we place an 'x' in the column of the first decision and the row of the second. Figure 1 shows two hypothetical DSMs for a laptop computer consisting of four components: the drive system, the main board, the LCD screen, and packaging. Figure 1(a) depicts the design before modularization. There are many out-of-block x's both above and below the main diagonal. Zooming in on the matrix, we see that a decision about the main board affects a decision about the LCD screen, as indicated by the circled 'x' below the main diagonal. Changing the LCD screen decision in turn affects another

Figure 1 The process of modularization. Reproduced from Baldwin, Carliss Y., Clark, Kim B., 2000. Design Rules. The Power of Modularity, vol. 1. MIT Press, Cambridge, MA, pp. 50, 74.

decision on the main board. The flow of decisions thus forms a loop (shown by arrows) between the main board and the LCD screen. Hence the design process must cycle between the two components, adjusting decisions for each until the components are fully compatible.

The laptop design (and corresponding design process) can be modularized in the following way. First, designers must identify the technical cause of each unwanted dependency: why exactly does decision (1) concerning the main board affect decision (2) on the screen? Then they must resolve the potential conflict by formulating a 'design rule' or 'standard' that eliminates the dependency. Then, as long as each group of component designers stays within the constraints of the design rules, they are free to make decisions independently of the other groups.

The technique of removing unwanted dependencies via design rules is a generalizable procedure. When this strategy is consistently pursued, dependencies across components become sparser, and the system as a whole becomes 'near decomposable,' that is, tightly connected within components and loosely connected across components. Figure 1(b) shows a characteristic DSM after modularization. In this idealized picture, there are no out-of-block dependencies, indicating that work on each component can take place independently of the others. Hierarchical dependencies on design rules, indicated by new arrows, have replaced cyclical dependencies between component decisions. There are also new sets of activities, indicated by new blocks in the DSM. Design rules must be established and communicated at the beginning of the process, and system testing and integration are needed at the end of the process to bring the modules together, test the system, and work around unforeseen incompatibilities.

The following lessons can be learned from observing modularization as a process in varying contexts and over time. First, the benefits and costs of modularity vary across artifacts, technologies, and time. Whitney (2004) has argued that benefits tend to be high and costs low for digital and electronic artifacts, while electromechanical artifacts that manage large amounts of power or heat are intrinsically more difficult to split into independent subsystems. The case of Unix also shows that successful modularizations depend critically on prior knowledge of specific interdependencies and how to address them via hierarchical design rules.

Consumer preferences matter too. Modularity is most valuable when consumers value the option to mix and match components to adapt a system to their own needs or to accommodate later additions and upgrades. It is not worth modularizing if all consumers desire the same thing, indeed, it then makes sense to assemble separate components and sell them as an indivisible unit.

Finally, it is worth noting that technological progress does not always lead in the direction of higher levels of modularity. Adding interdependencies between components can lead to higher levels of performance and efficiency. For example, in the case of bicycle drive trains, Fixson and Park (2008) document a significant improvement in the precision and ease of use for 'index-shifting' systems in which all parts of the drive train are co-specialized. Introduced by Shimano in 1984, the nonmodular index-shifting systems quickly replaced older modular systems.

Modularity and Organizations: The Mirroring Hypothesis

Modularity and the process of modularization are important topics for the social sciences because of the impact of modularity on the division of knowledge, the organization of work,

the boundaries of firms, and ultimately industry structure. There is strong overlap between Parnas' definition of a module as a 'work assignment' and fundamental questions of organization and economic theory. von Hippel (1990), building on Simon and Alexander, proposed that information processing costs in organizations would be minimized if tasks were partitioned at points of low problem-solving interdependence. In other words, in assigning tasks to individuals or groups, modules should not be split, but kept together. Henderson and Clark (1990) turned this normative recommendation into a prediction. They defined organizational structure as being made up of communication channels, information filters, and problem-solving strategies and then asserted "organizations are boundedly rational and, hence, their knowledge and information-processing structure come to mirror the internal structure of the product they are designing" (p. 27). Thus the theory of correspondence between the modular structure of artifacts and the structure of organizations has come to be called 'the mirroring hypothesis.'

von Hippel and Henderson and Clark looked only at organizational structure within firms. Langlois and Robertson (1992[2003]) were the first to see that modularity could affect the division of labor across firms, hence the structure of an industry. Modular systems, they said, provide consumer choice in the selection of components, and thus can give rise to decentralized networks of producers whose products worked together based on common standards of compatibility. "By allowing specialist producers … to concentrate … on particular components, a modular system thus enlists the division of labor in the service of innovation" (1992[2003, p. 84]). They supported their arguments by recounting the impact of modularizations on industry structure in the stereo records and personal computer industries.

Sanchez and Mahoney (1996[2003]) unified and extended these arguments. Echoing Henderson and Clark, they suggested that "although organizations ostensibly design products, it can also be argued that *products design organizations*, because the coordination tasks implicit in specific product designs largely determine the feasible organizational designs for developing and producing those products" (1996[2003, p. 363], emphasis in original). They defined a modular product architecture as one that used standardized interfaces to achieve flexibility in configuration. Such architectures would allow a firm to "source components through loosely coupled networks," leading to "increasingly dynamic product markets" and "previously unattained levels of product variety and change" (1996[2003, p. 375]). In common with other writers in the mid-1990s, Sanchez and Mahoney were strong advocates of the modular approach to product design and saw practically no limits to its applicability. Like the Internet and the dot.com boom, modularity was part and parcel of the emerging new economy. Its failures and inherent risks (described above) were not then widely known or appreciated.

Why is mirroring a plausible hypothesis? In Baldwin's (2008) article on "Where do transactions come from?" I explicitly consider the impact of modularity on transaction costs and firm boundaries. Module boundaries are points where 'mundane transaction costs' are low; thus, other things being equal, they are attractive points to locate transactions between autonomous agents. It is possible to place transactions within modules, but potential agency and monitoring costs will be high, hence such placements generally will be disadvantageous. Work within modules is best conducted in a 'transaction-free zone.'

It is also possible to group several modules within the boundaries of a single corporation. But in this case, if the corporation favors its internal suppliers, it will lose the option value of seeking the best or lowest-cost components (Jacobides, 2005). Conversely, if the upstream business units are prohibited from selling to external customers, they may lose out on scale economies and fall behind in terms of technology and product performance.

Within the boundaries of a single firm, strict mirroring can be hard to achieve because of geographic constraints and organizational rigidities, especially given a changing product architecture. At the same time, modern information and communication technologies make it easier for geographically dispersed teams to coordinate work on a single module. Repeated interactions can lead to relational contracts and cooperation even in the absence of trust-inducing face-to-face interaction. Thus it is best to view mirroring as a cost-minimizing, ideal form of relationship between product architecture and organizational structure.

Two types of deviation from mirroring are possible and have different consequences (Colfer and Baldwin, 2010). First, a modular organization (for example, a geographically dispersed group of individuals or a set of autonomous firms) may undertake to design and produce a nonmodular product. Lack of mirroring will then result in increased coordination and/or transaction costs and failures arise because of insufficient communication or misaligned incentives. Second, a nonmodular organization (for example, a collocated team or a single firm) may undertake to design and produce a modular system. In this case, the organization may fail to perceive or ignore opportunities to reduce cost or enhance performance by adopting modular solutions from outside the organization.

An especially insidious version the second failure can arise when a nonmodular organization fails to perceive the value of modularity and makes the system less modular than it needs to be from a purely technical standpoint. For a nonmodular organization, maintaining module boundaries and interfaces is costly and may be viewed as unnecessary in the short run. Conflicts can be settled in an ad hoc fashion via direct communication and coordination between the affected parties. The result is a system with high levels of interdependence between elements: one that *ex post* looks more like **Figure 1(a)** above than **Figure 1(b)**.

If the options associated with modularity (variety, configurability, upgradability) are highly valued by consumers, the less modular systems will turn out to be uncompetitive with modular systems and disappear from the market. In such cases, the industry will come to be organized as a set of horizontal, complementary layers with different firms competing in and dominating each layer (Grove, 1996; Baldwin and Clark, 2000).

MacCormack et al. (2012) show that software code developed within firms is significantly less modular than

functionally equivalent software developed by geographically dispersed, autonomous individuals working in open source communities. Thus the mirroring hypothesis holds in this study: software developed by less modular organizations is less modular than dictated by purely technical considerations, and vice versa. However, it cannot be inferred from this study that the nonmodular systems are suboptimally structured. Although nonmodular products may suffer from lack of variety, configurability, and upgradability, there may be compensating benefits to firms in terms of lower cost, higher performance, and better protection of intellectual property (Henkel et al., 2012). Nevertheless, because mirroring between product and organizational structure is a low-cost alternative, especially in the short run, nonmodular organizations may create nonmodular products by default. If the benefits of modularity are deemed to be competitively significant, then managers must intervene by either imposing (and enforcing) modular design rules or by breaking up the nonmodular organization in ways that enforce information hiding between subgroups.

If deviations from strict mirroring are possible, then the frequency with which mirroring is observed and the circumstances of its presence or absence become important empirical questions. Colfer and Baldwin (2010) surveyed 102 studies of development projects in which both the modular structure of the system and organizational ties (geographic collocation and common employment) were disclosed in sufficient detail to infer whether mirroring was present or not. The sample included 22 within-firm studies, 62 across-firm studies, and 18 studies of open source communities. They found evidence of mirroring in just over two-thirds (69%) of the studies, although in a few cases the evidence was mixed. However, evidence of mirroring was noticeably weaker in the open source subgroup, where 68% (11 out of 18) studies were not supportive of the hypothesis.

Of the 32 studies that were not supportive, four cases involved collocated contributors employed by a single firm designing modular systems made up of independent components. In all of these cases, modularity was an explicit goal of the design effort, and a great deal of attention was paid to design rules. (One of these groups was the task group that designed the architecture of System/360, discussed earlier.)

In contrast, 28 of the 32 cases involved contributors who were not collocated and/or employed by the same firm collaborating to develop highly interdependent, nonmodular systems. Consistent with the idea that mirroring is a low-cost way to achieve the coordination and cooperation needed to complete interdependent tasks, all of these cases involved high levels of investment in tools that made it easy to share information and resolve conflicts rapidly as well as social mechanisms to build trust and encourage cooperation among the participants.

Conclusion: Open Research Questions

At this point, a number of open research questions remain, and I will close this article by mentioning a few of them. First, we need to know which types of sociotechnical systems are amenable to modularization and why. In some contexts, modularization appears irresistible; in others, there is no discernible trend; while in other cases, nonmodular systems have taken over the market. Successful modularizations appear to be enabled by (1) physical properties of the system (Whitney, 2004) and (2) knowledge of the relevant interdependencies (Baldwin and Clark, 2000; MacDuffie, forthcoming). Consumer preferences also play a role (Schilling, 2000[2003]), and firms may choose different degrees of modularity as a matter of competitive strategy (Fixson and Park, 2008; Henkel et al., 2012). But up to now, decisions on where and when to modularize have been ad hoc. A comprehensive theory that identifies the relevant variables and contingencies would go a long way toward preventing costly mistakes (MacDuffie, forthcoming).

Such a theory would also allow us to better understand and predict industry structure. Nonmodular systems often give rise to vertically integrated industries, in which a few firms strive to coordinate a pipeline of products that compete in the end-product market. Highly modular systems in contrast give rise to 'horizontally layered' industries in which many firms make complementary modules that jointly rely on open standards (Grove, 1996; Jacobides and Tae, 2012). In such industries, firms must actively manage their relationships with autonomous complementors, both large and small (Gawer and Henderson, 2007). They must decide which modules to keep closed as a source of profits, and which to open as a means of increasing system value (Henkel et al., 2012). Further empirical and theoretical work is needed to understand the competitive forces and dynamics at work in these highly distributed technical 'ecosystems' where competition between complementors is the rule.

Finally, in both modular and nonmodular systems, we need to better understand the reasons for and against mirroring. As argued earlier, mirroring should be regarded as an economic and strategic choice. It is sometimes advantageous for a tight-knit team to create and maintain a highly modular system, but this will not happen by default. Tools for visualizing and measuring modularity and enforcing modular boundaries are thus needed to make this a strategic option for firms. Conversely, geographically dispersed teams and/or autonomous individuals often need to collaborate to create nonmodular systems. In addition to opting for highly modular systems, open source software communities have also invested in tools and social practices, based on openness and technical transparency, that promote collaboration *within* modules (Raymond, 1999). Outside of software, however, this work is just beginning (cf. Dawson et al., 2012).

Although many complex systems exhibit modularity, it is a relatively new focus of research in the social sciences. The process of modularization was invented in the mid-1960s to solve the twin problems of complexity and costly upgrades caused by IBM's numerous incompatible product lines. Thereafter, the process has been applied many times, sometimes successfully but also with some notable failures. Through studying these experiments, scholars have developed a powerful and coherent economic theory of modular systems, which explains how modularity creates value and how and why modular systems evolve. The theory also

addresses the relationship between technological modularity and organizational structure through the mirroring hypothesis, which provides testable predictions about the location and design of transactions and the impact of successful modularizations on industry structure. However, more work is needed to develop a discriminating theory that can predict when and where modularizations are feasible and worthwhile to learn how firms compete in horizontally layered industries and to develop tools, organizational mechanisms, and social practices that will permit firms to relax the constraints of mirroring when it is advantageous to do so.

Monasticism: West and East

This article is reproduced from the previous edition, volume 15, pp. 9973–9976, © 2001, Elsevier Ltd.

Abstract

Monasticism, defined inclusively here to incorporate all modes of religious life from the hermit to the contemplative and active religious orders, can be found throughout all the major religious traditions. The monastic vocation, open to male and female alike, has been particularly prominent in Christianity and Buddhism and monastic organizations and institutions have had a great influence on civilizations and societies where these faiths have become powerful. Monastic life entails regular prayer, regimes of self-discipline, and works of charity. Occidental monasticism tends to inner-worldly activism, whereas oriental monasticism emphasises other-worldly mysticism. Religious virtuosi typically follow a Rule established by their charismatic founder(s). Each religious order and religious congregation has its own distinctive spiritual 'way' and apostolate (teaching, nursing, contemplative prayer). Different ages are associated with different 'styles' of religious life from the desert solitaries, to the great monastic centres of the Middle Ages, to the international missionary congregations of the modern era. Approaching the third millennium of monasticism, religious life west and east is at a crossroads as traditional forms confront novel experiments in the consecrated life.

Introduction

'Monasticism,' derived from the Greek word *monos* meaning 'alone,' is defined inclusively here to incorporate all forms of vocational commitment to religious life. It may embrace the reclusiveness of the solitary desert anchorite, the coenobitical 'flight' of the self-governing rural ashram, monastery, or convent, or the inner-city apostolates of households of professional catechists and ordained welfare workers. Throughout the histories of the major world faiths, countless religious devotees have 'set apart' their lives 'in' but not 'of ' the world within religious 'quasisects' adhering to particular theological traditions of 'training the soul.' From the Essenes of ancient Judaism, through the myriad Christian religious orders and religious congregations, to Sufi and Sanusi Islamic brotherhoods, or Buddhist and Hindu monks, monasticism provides contexts in which to study the religious mediation of the social bond and explore the variety of forms in which the quest for spiritual perfection impacts upon lifestyle, social organization, culture, and society.

The Religious Life

For Weber, the life of the monk, the religious virtuoso *par excellence*, is in direct contrast to that of the warrior, albeit both vocational forms of life exhibit a primitive communism valorizing a segregationist ascetic ethic of celibacy, poverty, and fraternal solidarity. Warrior-monks – Hospitallers, Templars, Teutonic Knights, Samurai – have existed within the great religious traditions as attempts to integrate the call(ings) to arms and alms. However, the military life consecrated to violence and the religious life dedicated to the peaceful pursuit of an interior spiritual state and the prefiguration of the kingdom of God usually have existed in mutual tension as separate 'ways'. Like militarism, monasticism typically cultivates a compliance culture characterized by pervasive regulatory structures for the discipline of the body together with elaborate command hierarchies demanding uncritical obedience to legitimate superiors (*'alter Christi,'* in the case of Christian religious orders) as a mark of the fidelity and successful socialization of conscripts and volunteers.

Detached from the responsibilities of marriage and family, monastic life provides opportunity for both personal sanctification and an exemplary 'life for others.' Be it through life-long observance of 'the nine canonical hours' or the daily round with the begging bowl of the temporary Buddhist monk, 'the ascetic death-in-life' (Weber, 1963), serves to 'mortify the flesh' and 'raise the mind, heart and soul to God.' This quotidian self-discipline develops a unified life ofwork and prayer where the contemplation of cloister, cell, or convent integrates with the labors of field, study, or hospital ward. Weber (1963) characterized occidental monasticism as 'the disciplined army of a rational bureaucracy of office' and deemed it a mode of 'asceticism directed toward the outer world.' By contrast, 'oriental monasticism' was considered to be 'of magical character,' dominated by the innerdirected mysticism of fakirs, sages, and mystagogues.

Becoming a 'religious,' be that a scholar monkpriest, enclaustrated nun, nursing sister, or liqueurmaking brother, entails a lengthy process of formation through various graded orders of membership as entrants pass, usually via a formal investiture ceremony ('the taking of the habit'), from novice through to 'full profession.' Under the watchful eye of experienced 'directors of souls,' entrants to 'the vowed life' are absorbed within a distinctive tradition of discipleship having its own idiosyncratic mores, prayer routines, division of labor, and 'heroic' exemplars such as saints and martyrs. Thus, each separate religious 'clan' transmits its own spiritual 'disciplines' and cultural inheritance to incoming generations of recruits whose individual members 'become' religious of a given stamp: Carthusian, Carmelite, Community of the Resurrection, Shinto, Sufi, Tibetan Buddhist, and so on. Distinct 'family resemblances' unite the members of the same monastic dynasties across time

and space. This religious cultural capital manifests not only as material symbolic externals such as the cut and color of the diverse religious costumes, but also in the characteristic religious responses associated with the various spiritual 'paths' and their associated forms of life. To the outsider, all monks and nuns may look alike and engage in much the same works of divine service and charity. To the insider, however, a de la Salle Teaching Brother and a Franciscan friar are as different as chalk and cheese. A howling Dervish is not a silent Cistercian Trappist.

Civilizational Mission

Civilizations east and west have been marked inerradicably by their monastic patrimonies that have been formative at critical renewal points in the histories of peoples, empires, and cultures. Nisbet (1973) goes so far as to opine: 'Without any question, it seems to me, the monastery, especially as it was conceived by Benedict, is the true source of most of our Western ideas of community achieved through the processes of withdrawal and renewal.' Across the faith traditions east and west, monasteries as centers of 'godliness and good learning' (Leclercq, 1961) have been power-houses of liturgical, musical, and architectural creativity sites of practical wisdom in agriculture, animal husbandry, and horticulture (grape growing and bee-keeping being renowned monkish specialisms) (*see* Religion and Economic Life); pre-eminent throughout the religious traditions in the arts and sciences of calligraphy, printing, and librarianship; and, as 'experiments in living,' 'prophetic' centers of innovation in modes of self-governance and welfare administration. Despite a reputation for social conservatism, religious virtuosi from all the world faith traditions across all five continents have participated in diverse independence movements and human rights campaigns.

As a force in the development of the western social order, monasticism has spawned many regional 'styles' with their own distinctive roots and Rules but with considerable syncretism in evidence (Knowles, 1969). In the course of time, 'Celtic' monasticism, itself deriving from the Egyptian eremetical exemplars (Antony and Pachomius) fused with the reverence for learning of the Greek and Frankish scholar-monks, such as Basiland Cassianto develop the high Latin culture that was the main conduit of Christianity from the last days of the Roman Empire to the initial centuries of Christendom in the early Middle Ages. Missionary monks inspired by St. Patrick and St. Columbas took the Christian gospel into the heartlands of European tribal society in the sixth and seventh centuries. From the eighth to the eleventh centuries ('the Benedictine centuries'), the proliferation of daughter monasteries of Benedict's Monte Cassino (founded 529) created the network of organization and intelligence that shaped the character and ethos of medieval European civilization. The religious culture of early modern urban development in the thirteenth and fourteenth centuries was much influenced by the preaching friars (Dominicans, Franciscans, Augustinians) of the Mendicant Orders (Lawrence, 1994) (*see* Christianity, Origins of). Throughout Asia and the Far East the monasteries of Theravada Buddhism had comparable influence (Silber, 1995) (*see* Buddhism).

Styles of Life

The 'contemplative' and 'active' styles of religious life rarely are walled off entirely from each other. The 'world' knocks at the monastery gates in every era. Pontiffs and prelates have sought the support of abbeys and nunneries in the promotion of this or that ecclesial cause from prayers for the crusades to theological backing in the extirpation of heresy. Monarchs and nobles have found ways to secure preference and placement for one of their number in the governmental and suffrage systems of religious life. Paradoxically, these attractions and achievements have at times led to monasticism assuming considerable economic and political power (*see* Religion: Mobilization, and Power) be it that of the great medieval religious foundations (Grande Chartreuse, Cluny, Citeaux, Monte Cassino) with their vast benefices and endowments; or the self-governing republic since 1052 of the influential monastery of Mount Athos in northern Greece; or the three centuries of state control assumed by the Dalai Lama, the chief abbot of Tibetan Buddhism; or the impact since 1837 of the Senusi Islamic brotherhood on Sudan and the eastern Sahara. There is a continuous tradition of criticism of the worldly foibles and contradictions of monastic elites down the ages, from Vigilantius (fourth century), through Chaucer, Erasmus, Luther, and Calvin, to Voltaire and modern anticlerical republicanism worldwide. Liberation theology and a spate of contemporary novels and films directed against 'new world theocracies' (the Paraguayan Reductions) and colonial 'foreign missions' sustain the iconoclastic suspicion of monastic imperialism.

Successive waves of new religious foundations have been launched by charismatic (*see* Charisma and Charismatic) religious founders animated by a utopian 'return to sources' *(ad fontes)* from which 'scriptural primitivism,' the combined attack on abuses within the Church and world, have been prepared down the centuries. The inherent tension between its this-worldly and other-worldly parameters accounts in great measure for the transformative capacities of monasticism which owes its survival and dynamism to an ongoing internal reform impulse (the Gregorian Reforms, for instance). Following the upheavals of the Protestant Reformation ('the dissolution of the monasteries') and the French Revolution, Roman Catholicism invested heavily in 'apostolic orders' (Jesuits, Daughters of Charity) and missionary teaching congregations (Sallesians, Marists) which served as 'the pope's battalions' in the Tridentine 'counter-modern' offensive. The nineteenth-century Oxford Movement saw fit to revive monasticism within Anglo-Catholicism (Hill, 1973). Come the age, come the religious order. The *aggiornamento* of the Second Vatican Council (1962–65) with its emphasis on 'adaptation to the signs of the times' and 'a preferential option for the poor' (Sweeney, 1994) is the most recent expression of the sporadic self-reform tendency in religious life to check the mixed fruits of sanctity's success, social, and theological drift.

Each new age of monastic life and religious congregations addresses the perceived apostolic needs and ecclesiastical interests of the epoch be that for grand monastic citadels, hostels for crusaders and pilgrims, sanctuaries from plague and persecution, hospitals, schools, orphanages, hospices, food kitchens, or way stations for state policies of care in the community. Monasticism serves as a ligature binding civilizations east and west to their pasts and a bridge across which lessons of the religious quest are passed over into civil society.

Not surprisingly, militant secular regimes (*see* Secularization) have found pretext to sequester monastic assets and secularise (and worse) religious personnel. Monasticism and the religious orders provide the great world religions with multiple and mixed benefits: an outlet for 'charisms' to flourish then 'routinize'; an opportunity context for a specialized religious 'division of labor'; social space to cultivate a realm of inter mediate associational life – collegia – within the complex organic ecclesiastical commonwealth (the *communitas communitatum*) without need for secession from the Mother Church.

Sign of Contradiction

If, on the one side, the religious institutes represent *gemeinschaft* in its most comprehensive guise (anticipatory democracy, brotherhood of equals, protofeminist sisterhood), on the other side, monastic life can exemplify the 'total institution' as escapist flight into infantile dependency and social parasitism. As a 'sign of contradiction,' monasticism and religious life west and east, appear destined to live out these two contrary images and appeals. As many established religious orders enter the 'terminal' stage in the monastic life-cycle (Hostie, 1972) marked by membership hemorrhage, aging and low, erratic recruitment (Ebaugh, 1993), the third millennium is likely to see novel forms of monasticism – mixed gender lay communities; gay and lesbian institutes; multifaith congregations – bearing witness 'against all reason' and the 'possessive individualism' of secular modern consumer society to the resilience and revitalization (Cada et al., 1979) of 'the consecrated life.'

Monetary Policy since the 2007–2009 Financial Crisis

Benjamin M Friedman, Harvard University, Cambridge, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Monetary policy is one of the two principal means (the other being fiscal policy) by which government authorities in a market economy regularly influence the pace and direction of overall economic activity, importantly including not only the level of aggregate output and employment but also the general rate at which prices rise or fall. This article updates the earlier article on 'Monetary Policy' (link) to take account of the extraordinary developments initially triggered by the 2007–09 worldwide financial crisis and then following in the aftermath of the crisis. With short-term interest rates in most advanced industrialized economies at or near zero, soon after the crisis began, central banks have been forced to seek out new ways of carrying out monetary policy. In part these new policy tools have involved heightened efforts to influence market participants' expectations of future monetary policy actions. In other respects they have involved an expanded role for a central bank's asset holdings, rather than its outstanding liabilities which had previously been the main focus of monetary policy. Both directions raise important questions about how monetary policy affects economic activity and how best to carry out this important aspect of economic policymaking.

Monetary policy is one of the two principal means (the other being fiscal policy) by which government authorities in a market economy regularly influence the pace and direction of overall economic activity, importantly including not only the level of aggregate output and employment but also the general rate at which prices rise or fall. Even before the 2007–09 financial crisis, the predominant trend over much of the prior half century had been to place increasing emphasis on monetary policy (and correspondingly less on fiscal policy) for these purposes. In many countries, events since the crisis further shifted this balance toward monetary policy, as central banks initially acted to prevent the crisis from developing into a disastrous economic collapse and then sought to foster recovery from the downturn to which the crisis led. On both counts the specific actions that many central banks took and the broader directions that they charted during this period broke new ground in monetary policymaking. At the same time, the crisis experience highlighted the role that monetary policy plays in ensuring 'macroprudential stability' – that is, stability of the financial system as a whole, in contrast to preventing the failure of any individual financial institution.

The 2007–09 financial crisis and the protracted economic downturn that it triggered in many of the world's advanced industrialized countries represented one of the most significant economic events since World War II. The collapse of major financial firms, the decline in asset values and consequent destruction of paper wealth, the interruption of credit flows, and the loss of confidence both in firms and in credit market instruments were all extraordinary. In many countries the real economic costs – in terms of reduced production, lost jobs, shrunken investment, and foregone income and profits – exceeded that of any postwar decline. Further, in many countries the recovery from the downturn proved frustratingly slow. It is hardly surprising that monetary policy in many countries responded to these events in extraordinary ways (Borio and Disyatat, 2010; Bernanke, 2012a,b).

Special Lending to Financial Institutions

Because the 2007–09 crisis grew out of failures in the credit markets – in the first instance, the market for residential mortgages in the United States – and because many major financial institutions held claims on these troubled instruments in sufficient volume to threaten their viability, the first response of many governments and central banks was to act to prevent the kind of cascading failures that had turned the downturn of the early 1930s into the Great Depression. Very early in the crisis many central banks instituted special facilities for lending to banks and in some cases to other financial institutions as well. In December 2007, the U.S. Federal Reserve System established a Term Auction Facility to channel extra central bank lending, and on unusually favorable terms (as well as with anonymity, to avoid the reputational damage often consequent on large-scale borrowing from the central bank), to commercial banks doing business in the United States. Early in 2008, the Federal Reserve established two additional facilities, enabling it to lend against a broader class of collateral and to lend to nonbanks. As early as August 2007, the European Central Bank (ECB) had undertaken a special intervention to inject liquidity into the Eurozone banking system and had declared its readiness to provide unlimited further liquidity if needed. In September 2008, the ECB undertook a further special 'term refinancing' operation (in other words, lending to banks for longer than normal). In May 2009, the ECB changed its method of regular weekly policy operations to remove the previous limit on banks' access to central bank funds, thereby making liquidity available on an unlimited basis at the main refinancing rate. It also lengthened the maturity of its lending, expanded the range of eligible collateral, and introduced new facilities that enabled it to transact with a broader range of counterparties. Later, at the end of 2011, the bank acted to prevent a renewed liquidity crisis among Eurozone banks by

offering banks 3-year financing under a new 'long-term refinancing operation.' In April 2008, the Bank of England introduced a special liquidity scheme to enable struggling U.K. banks to exchange illiquid assets for assets like Treasury bills that could then be used as collateral for further borrowing. The Bank of Japan had already been employing such extraordinary policy measures for some years by the time the 2007–09 crisis hit. These steps included an expanded securities lending facility, a broader range of collateral (including private securities) eligible for central bank lending, and even some direct funding for Japanese corporations.

Lending by central banks to banks, and even to nonbank financial institutions, was not new in the 2007–09 crisis. Nevertheless, the actions that the major central banks took in response to the crisis were different from what they had done in the past, both in scale and in scope. (In addition to these central bank actions, governments in some countries took highly unusual steps to prevent the failure of a variety of bank and nonbank institutions, even including nonfinancial firms. The U.K. government, for example, took an 81% share in Royal Bank of Scotland, and at the peak the U.S. government owned more than one-third of the equity in Citigroup and more than 90% of that in AIG. The U.S. government also rescued from failure two of the three large American automobile manufacturers (Cecchetti and Disyatat, 2010; Ashcraft et al., 2012)).

Conventional Monetary Policy, Down to the Zero Lower Bound

Once it became apparent that the financial crisis was likely to have significant effects beyond the financial markets, depressing output and employment in many economies (with yet further feedback onto the viability of their lending institutions), central banks turned to expansionary monetary policy in the usual way – that is, by lowering short-term interest rates. As late as September 2007, the U.S. Federal Reserve System's target for the federal funds rate, its customary policy rate, had been 5¼%. After a sequence of reductions, in December 2008, the Federal Reserve adopted a target range of 0–¼%. The ECB lowered its main refinancing rate from 4¼% as late as October 2008 to 1% in May 2009. Beginning from 5¾% throughout the summer and fall of 2007, the Bank of England first lowered its official bank rate in December of that year and did so in repeated steps until it reached ½% in March 2009. In Japan, where short-term interest rates had already been at very low levels for years, owing to the economy's stagnation and the gradual average decline of prices, the Bank of Japan lowered its uncollateralized call loan rate from ½% in October 2008 to just 1/10% in December of that year.

The central banks of the advanced high-income economies also coordinated these actions to an extraordinary extent. In October 2008, for example, six central banks – the U.S. Federal Reserve System, the Bank of Canada, the Bank of England, the ECB, the Swiss National Bank, and the Sweden's Riksbank – simultaneously announced a ½% reduction in each bank's policy interest rate. The Bank of Japan could not match this reduction because its policy interest rate was already so low, but it nevertheless publicly expressed its support for this action.

Especially in the United States and Japan, these actions effectively placed the central bank's policy interest rate at the practical lower bound. Because investors in most economies can always earn a zero nominal interest rate by holding currency, which is risk-free apart from physical security concerns, the central bank cannot force the expected nominal return on any other asset below zero; investors would merely substitute holdings of currency instead. In most periods of weak economic activity in the past, even with easier monetary policy the nominal interest rates on short-term market instruments never reached the zero lower bound because price inflation was sufficiently rapid that the central bank could implement whatever negative real interest rate (the nominal rate minus expected price inflation) it chose to achieve the desired stimulus to economic activity while nominal rates remained above zero. But by the time of the 2007–09 crisis, inflation had been low, in most of the industrialized world, for some years. As a result, the initial actions central banks took to stimulate their economies quickly pushed nominal short-term interest rates to, or close to, the zero lower bound. Many central banks therefore turned to other – in many cases, highly experimental – ways of providing further economic stimulus (Krugman, 1997; Bodenstein et al., 2012; Chung et al., 2012; Ball, 2013).

Forward Guidance on the Policy Interest Rate

One approach that some central banks had tried before (for example, the Federal Reserve System in the early 2000s), was the use of public statements intended to influence market participants' expectations of the *future* level of the policy interest rate over some economically significant time horizon. Once the policy interest rate approached the lower bound in the 2007–09 financial crisis, many central banks turned almost immediately to this kind of 'forward guidance' with respect to their own future actions. Moreover, as central banks attempted to place greater reliance on this policy tool during the crisis and its aftermath, they continually experimented with various ways of expressing their intentions.

When the Federal Reserve reduced its target for the federal funds rate to 0–¼%, in December 2008, the Open Market Committee (the Federal Reserve group responsible for such decisions) publicly stated that "the Committee anticipates that weak economic conditions are likely to warrant exceptionally low levels of the federal funds rate for some time." The Committee repeated substantially the same public statement following each meeting that it held through June 2011. In August 2011, it then switched to a more explicit, calendar-based statement that "the Committee currently anticipates that economic conditions … are likely to warrant exceptionally low levels for the federal funds rate at least through mid-2013." Thereafter, the Committee extended the specific horizon for this

forward guidance several times, by late 2012 indicating the anticipation of low short-term interest rates 'at least through mid-2015.' In December 2012, the Committee shifted to yet a new form of statement explicitly conditioned on observed and forecast economic outcomes rather than a specific calendar date: "the Committee … currently anticipates that this exceptionally low level for the federal funds rate will be appropriate at least as long as the unemployment rate remains above 6½%, inflation between 1 and 2 years ahead is projected to be no more than a half percentage point above the Committee's 2% longer-run goal, and longer-term inflation expectations continue to be well anchored." In January 2014, with the latest reported unemployment rate down to 6.7%, the Open Market Committee changed the language of its regular statement once again, to emphasize that if the unemployment rate were to fall below 6½% this event alone would not necessarily trigger an increase in the target federal funds rate: "In determining how long to maintain a highly accommodative stance of monetary policy, the Committee will also consider other information, including additional measures of labor market conditions, indicators of inflation pressures and inflation expectations, and readings on financial developments. The Committee continues to anticipate, based on its assessment of these factors, that it likely will be appropriate to maintain the current target range for the federal funds rate well past the time that the unemployment rate declines below 6–1/2%, especially if projected inflation continues to run below the Committee's 2% longer-run goal." In March 2014, the Committee changed its forward guidance again, deleting the reference to a specific unemployment rate altogether and indicating a continuation of the low interest rate policy even after the achievement of the 6–1/2% level: "In determining how long to maintain the current 0–¼% target range for the federal funds rate, the Committee will assess progress – both realized and expected – toward its objectives of maximum employment and 2% inflation. This assessment will take into account a wide range of information, including measures of labor market conditions, indicators of inflation pressures and inflation expectations, and readings on financial developments. … The Committee currently anticipates that, even after employment and inflation are near mandate-consistent levels, economic conditions may, for some time, warrant keeping the target federal funds rate below levels the Committee views as normal in the longer run."

Other major central banks likewise employed public statements about their future policy actions, although not synchronously with the Federal Reserve. The Bank of Japan, faced with deflationary conditions, had already been using a form of forward guidance as early as 1999, and in 2001 had strengthened the language it used to refer not just to declining prices but real economic activity as well. The bank returned to this tactic after the crisis as well. In October 2010, it announced that the policy interest rate would remain at zero until the economy had regained price stability, and in April 2013, it further linked the zero interest rate to realization of the bank's new 2% inflation target. The Bank of England turned to forward guidance only in August 2013, announcing that its Monetary Policy Committee "intends not to raise Bank Rate from its current level of 0.5% at least until the Labour Force Survey headline measure of the unemployment rate has fallen to a threshold of 7% … ." In February 2014, the Committee indicated – in parallel with the Federal Reserve's statement the month before – that it would most likely keep the rate low even after unemployment reached 7% or below. The ECB made no explicit statement about future levels of its policy interest rate until July 2013, when (echoing what the Federal Reserve had done early on in the crisis) it announced that it intended to keep the rate low for an 'extended period of time.'

The purpose of this longer-horizon guidance on the policy interest rate, at each respective central bank, was not to help enforce the target for the policy rate itself – under conditions initially of the crisis and then the protracted slow postcrisis recovery this was unnecessary – but rather to influence market participants' expectations in such a way as to help lower the interest rates on longer-term securities, like mortgages and corporate bonds, by which households and firms finance their spending. Many investors can substitute between holding longer-term securities and holding a comparable-duration sequence of short-term instruments in their portfolios. Lowering the policy rate that investors expect to prevail in the future induces investors to seek to shift their holdings toward longer-term securities, thereby also lowering the longer-term interest rates that presumably matter for private economic activity. There is some evidence, from experience before the crisis as well as after, of effects on market interest rates associated with this kind of announcement. In addition, expectations that short-term interest rates would remain low for an extended time would plausibly encourage greater market demand for assets like equities, helping to raise their prices and thereby increase household wealth. On both counts, the goal was to stimulate aggregate demand for goods and services in the economy, and therefore boost output and employment from crisis-depressed levels. (By contrast, there have been some instances in which the effect of such statements of intentions regarding future central bank actions has been counterproductive from the perspective of the objective apparently motivating the statements in the first place. Most prominently, when Federal Reserve officials first referred publicly, in the spring of 2013, to the likely cutback and eventual termination of its ongoing bond purchase program (see Section Large-Scale Asset Purchases below), the immediate market reaction raised long-term interest rates by more than most estimates of the program's total effect to that time in lowering them (Gurkaynak et al., 2005; Levin et al., 2010; Justiniano et al., 2012; Kool and Thornton, 2012)).

Large-Scale Asset Purchases

With short-term interest rates effectively at the zero lower bound, many central banks also sought to bring down longer-term interest rates in ways that went beyond the expectational effect of forward guidance on the future

trajectory of the policy interest rate. Doing so led some central banks to become major purchasers of various kinds of longer-term assets – not for the purpose of expanding their liabilities, as under traditional monetary policy, but for the effect on asset prices and yields consequent on the purchases of the assets themselves. In effect, as a result of the crisis the focus of monetary policy switched from the liability side of central banks' balance sheets (providing currency and especially reserves) to the asset side (buying and holding financial instruments issued by other borrowers).

In the United States, the Federal Reserve System first began to purchase large quantities of unusual assets in October 2008, following the collapse of the market for commercial paper (unsecured short-term borrowing by private financial institutions and nonfinancial corporations) triggered by the failure of Lehman Brothers. Fairly quickly, the central bank accumulated $385 billion of commercial paper; its doing so stabilized what had become a dysfunctional market, thereby reducing the interest rate borrowers had to pay and also reviving the volume of new lending. In March 2009, the Federal Reserve instituted a new program to purchase securities backed by residential mortgages. By year-end, it had accumulated $900 billion of these securities, once again restoring functionality to a badly damaged market, and resulting in lower interest rates to borrowers as well as increased volume.

These purchases sharply increased the size of the Federal Reserve's balance sheet. By year-end 2008, total assets held were $2.2 trillion, compared to less than $900 billion at the beginning of 2007, although most of the increase consisted of advances to banks and other financial firms, and holdings of instruments like commercial paper acquired through directed facilities intended to support specific markets. At year-end 2009, total asset holdings were still $2.2 trillion, but in place of direct advances under special facilities the Federal Reserve had purchased large quantities of Treasury notes and bonds and, even more so, of mortgage-backed securities. By mid-2014–5½ years into the period of zero short-term interest rates – total assets held reached $4.3 trillion, more than quadruple the level at the beginning of the crisis.

Other central banks pursued similar policies, in either greater or lesser amounts. In May 2010, the ECB initiated a program to buy directly securities that it normally accepted as collateral in lending. In September 2012, the ECB converted the program to one of 'outright monetary transactions,' under which its purchases of member states' government bonds were to be permanent rather than temporary holdings. Under these programs the bank purchased enough assets, and did enough lending, that its balance sheet grew from €1.1 trillion at the beginning of 2007 to €3.1 trillion at year-end 2012. The Bank of England began its asset purchase program in March 2009 and progressively increased its volume of monthly purchases. By late 2012, the increase in the bank's balance sheet was proportionately even greater than that of the Federal Reserve: from £85 billion at the beginning of 2007 to more than £400 billion. In Japan, where the central bank had already engaged in policies that greatly expanded its balance sheet well before the crisis, the increase was initially smaller. But following the election of a new government in December 2012, together with the appointment of new leadership at the Bank of Japan the following spring and the bank's subsequent commitment to raising Japan's inflation rate to 2% per annum, the rate of increase accelerated abruptly: starting from ¥110 trillion at the beginning of 2007, the bank's total assets held reached ¥258 trillion by mid-2014.

The purpose of these asset purchases was sharply different from the usual working of central bank open market operations. There, the object is to reduce the market-clearing interest rate on central bank liabilities, taking advantage of the interest-elastic demand for central bank reserves on the part of banks and other reserve-holding institutions (see Section 2 of the 2000-article on Monetary Policy). Because the central bank must pay for any assets it acquires, open market purchases of assets are simply the way in which the central bank brings about an increase in the quantity of reserves that it supplies to the market. Whether the central bank frames the operation as choosing a larger quantity of reserves and letting the market determine the corresponding new (presumably lower) equilibrium interest rate, or choosing a lower interest rate and supplying whatever (presumably larger) quantity of reserves the market requires to get there, is irrelevant for this purpose. What matters in practical terms is the impact on the market-clearing short-term interest rate.

The point of the asset purchases that central banks made during and after the 2007–09 financial crisis, once short-term interest rates were already at or near zero, was plainly different. Now the object was to lower the interest rates that mattered more directly for the private sector's demand for goods and services, taking into account that no private sector borrower issues default-free obligations or finances its expenditures with overnight borrowing. On grounds of both maturity and default risk, private-sector obligations are not perfect substitutes for default-free overnight instruments in investors' portfolios. The return on the relevant private-sector obligations therefore depends on more than just the current level and expected future trajectory of the central bank's policy interest rate (typically an overnight rate, or some other very short maturity). In particular, it depends on the quantity of private-sector obligations that investors, collectively, must hold. Asset purchases by the central bank therefore add to the total market demand for private-sector securities, and so, for given supply, they raise the market price of these securities, thereby lowering the corresponding market-clearing interest rates.

In the ordinary open market operations that central banks carry out when their policy interest rates are not constrained by the zero lower bound, the volume of assets purchased is too small to have noticeable effects of this kind. But the asset purchase programs carried out by many central banks since the 2007–09 crisis have been several orders of magnitude larger, and most analyses of these purchases confirm that they have had such effects in sufficient size to exert a meaningful effect on the economy. Estimates of this policy's effectiveness in lowering long-term interest rates in the United States, scaled to a $600 billion asset purchase

(the size of the Federal Reserve's 'QE2' round of bond buying announced in November 2010 and carried out over the following 7 months), average about ¼ percentage point – not enormous, especially in light of conventional estimates of the effect of lower interest rates on aggregate demand, but a contribution to the economic recovery process that Federal Reserve policymakers were seeking. Moreover, the effect of lower long-term interest rates was probably reinforced by corresponding movements in equity prices and in the foreign exchange value of the dollar (although in the case of exchange rates any conclusion is necessarily conditional on the assumption made about the policy stance underlying the other currency).

Further, the composition of the assets that the central bank buys matters too. In the U.S. experience, the Federal Reserve bought not just long-term assets but mortgage-backed securities in particular; as of mid-2014, the Federal Reserve held $1.7 trillion of such securities, out of a total balance sheet of $4.3 trillion. The intended effect was to narrow the spread between the interest rates on mortgage borrowing versus comparable-maturity Treasury obligations, and thereby to arrest the downward trend in house prices as well as to stimulate new residential construction. In light of the role of the mortgage market as the epicenter of the 2007–09 financial crisis, with consequent effects on residential construction (U.S. homebuilding declined from 2.1 million new houses started in 2005 to just 554 000 in 2009) the central bank's desire to stimulate demand in this one sector of the economy in particular is easily understandable. Clear evidence on the effectiveness of these mortgage purchases on new construction is not yet available, but on the surface it appears that at least the attempt to narrow mortgage–Treasury interest rate spreads was effective.

Potential Risks from Large-Scale Asset Purchases: Price Inflation?

Because central banks have to pay for assets that they purchase, the large increase in asset holdings with which many of them responded to the 2007–09 crisis likewise meant an equally large increase in their outstanding liabilities. Economists who view the macroeconomy through the lens of central bank (or 'high powered') money supply therefore expected not just some increase in these economies' rates of inflation but a hyperinflation, perhaps even reminiscent of what occurred in Germany and Russia after World War I or in Hungary after World War II. Some well-known economists predicted just such a consequence of these extraordinary central bank actions.

But as of mid-2014, more than 5 years into the implementation of postcrisis policies, no such increase in inflation – not even a few percentage points – had appeared, in any of these economies. Even if inflation in these countries does pick up pace at some point, a response of some percentage points to this magnitude of increase in central bank liabilities, and only after a delay of more than half a decade, would still be sharply at variance with the core implications of standard quantity-theory models relating prices to central bank money. The central idea of the quantity theory, familiar from generations of textbooks prior to the crisis, was that doubling the quantity of central bank liabilities (or 'monetary base') would lead to a doubling of the price level. In some of the major economies, the quantity of central bank liabilities not just doubled but quadrupled. Correspondingly, several generations of empirical research in monetary economics, prior to the crisis, had documented the relationship between one or another economy's price level and the quantity of liabilities issued by its central bank. In light of the large magnitude of the expansion in central bank balance sheets during and following the crisis, however, together with the absence of any noticeable response from prices, it will be a long time before anyone will again be able to find economically sensible estimates, for any of the large high-income economies, from what were once standard empirical relationships between the price level (or its rate of change) and the quantity (or change) of central bank liabilities.

Potential Risks from Large-Scale Asset Purchases: Portfolio Losses?

Central banks normally take little risk. Most of the assets that they hold are usually limited to short-term obligations of their own governments. In advanced industrial countries, therefore, where the probability of the government's defaulting on its obligations is remote, the risk of loss to the central bank is minimal.

The assets that many central banks purchased during and after the 2007–09 financial crisis were different. Many were of longer term, and therefore subject to the risk of market price decline if interest rates were to rise. Some – for example, commercial paper in the United States, and mortgage-backed securities in the United States and the United Kingdom – were issued by private borrowers, and therefore subject to risk of potential default. (In some cases, however, private obligations bought by the central bank were guaranteed by the country's government; the mortgages bought by the Federal Reserve, for example, were insured by the U.S. federally sponsored credit agencies, which by then had been taken into receivership by the U.S. Government.)

Because central banks typically operate with very little capital, risk of significant loss on their asset holdings, either from fluctuation in the market value of longer-maturity obligations or from default by private-sector issuers, raises the prospect of a reduction in capital, and perhaps even a technical insolvency. As of mid-2014, no such losses had eventuated; instead, holding the securities that they purchased during and in the aftermath of the crisis had delivered record portfolio profits to those central banks that pursued this course. Once the financial effects of the crisis are in the past, however, and market interest rates return to a more normal structure (with short-term rates no longer at the zero lower bound), some losses of this kind are likely. Such losses would represent a form of negative seigniorage – in contrast to the record gains implicitly earned by taxpayers from 2008 to 2014 – and therefore ultimately impose a burden on the country's taxpayers.

Portfolio losses of this kind pose no real risk to the central bank itself, however. In contrast to a private bank or other

private financial institution, a central bank does not need positive capital to operate (Curdia and Woodford, 2011; Gagnon et al., 2011; Gertler and Karadi, 2011; Krishnamurthy and Vissing-Jorgenson, 2011; Friedman, 2015).

New Questions about the Future Conduct of Monetary Policy

The extraordinary actions that many central banks took during the 2007–09 financial crisis, and in the lengthy economic recovery following it, have raised a variety of new questions about the future conduct of monetary policy, once the effects of the crisis have finally passed. Three stand out as the most significant.

The Ongoing Usefulness of Forward Guidance

Central banks have increasingly relied on 'forward guidance' during this experience – that is, public statements about their own likely future policy actions, intended to shape the expectations of market participants – in part as a way to make monetary policy more effective when reductions in the policy interest rate are precluded by the zero lower bound. In principle, however, there is no reason not to resort to such statements as a supplement to ordinary interest rate policy once short-term interest rates are no longer constrained.

To what extent central banks will do so remains uncertain. The problem lies in the nature of speculative asset markets. Economists who study monetary policy often work with models in which the structure of the relevant expectations on the part of financial market participants and of private economic agents more generally is extremely simple (in some standard models the only aspect of monetary policy that influences economic agents' behavior is the central bank's long-term inflation target), but the world in which actual central banks operate is different. Even if the central bank steers its monetary policy according to a fixed inflation target, the Bank of England does, participants in the securities markets still want to know just how much departure from the inflation target policymakers will tolerate, and under what circumstances, before they decide to raise or lower the bank's policy interest rate, or buy or sell assets, or engage in any of a variety of other policy actions. If the central bank follows a more loosely defined inflation targeting regimen, as in the case of the ECB, or has explicit multiple policy objectives, as the Federal Reserve does, the opportunities for such speculation are all the richer.

Market participants are in the business of speculating, for profit, on the actions that the central bank takes and the timing with which it takes them. No matter what level of transparency and disclosure the central bank provides, therefore, unless it locks its policy trajectory into determination under a rigid formula, which it publicly discloses and commits to follow without departures, the market will inevitably want to know more than policymakers can possibly disclose. Even then, the central bank's no-departures commitment may well not be fully credible, so that market participants will continue to speculate about policymakers' actions – although in this case the speculation is framed in terms of whether, and if so under what circumstances, they will violate their pledge to adhere to the formula.

The Ongoing Usefulness of Asset Purchases and Sales

Parallel questions surround the potential future use of the other new monetary policy tool to which many central banks turned in the absence of ability to lower their policy interest rates: asset purchases. The value to monetary policy of the ability to influence long-term interest rates in general, and specific interest rates like the mortgage rate in particular, likewise does not vanish just because the short-term interest rate that the central bank normally uses as its policy interest rate is above zero and potentially subject to being lowered. Further, in contrast to forward guidance, the evidence on the effectiveness of such asset purchases is more clear-cut. As a result, there is a reasonable likelihood that, at least occasionally, central banks will continue to use some form of asset purchases – and, conversely, asset sales when the object is to raise long-term interest rates in order to restrain economic activity – once the zero lower bound is no longer binding.

Further, the potential usefulness of such purchases and sales is not limited to attempts to stimulate or restrain aggregate economic activity. During the years before the crisis, for example, when U.S. house prices were rising rapidly and homebuilding had likewise reached extremely high levels, many observers of monetary policy urged Federal Reserve policymakers to tighten policy in order to arrest the developing 'bubble' in the mortgage and housing markets. The frequently expressed concern, however, was that raising short-term interest rates was a 'blunt instrument' with which to attack an excess in one specific sector of the economy. By contrast, if the central bank can deploy its balance sheet separately from its setting of its policy interest rate – and, if a part of its balance sheet is its holdings of mortgage-backed securities, which it can either enlarge or reduce in order to lower or raise mortgage rates relative to other interest rates – it can take more directed action in the event of a situation like the one that preceded (and, in the eyes of many economists, precipitated) the crisis.

Keeping this new policy tool available in a symmetrical way, so that the central bank can make either asset purchases or sales depending on the needs of the economy, also has a bearing on the extent to which central banks should seek to return their balance sheets to the pre-crisis size – which for many would mean a large reduction – once their economies regain a more normal footing. Having sizable asset sales available as an ongoing tool of monetary policy requires that the central bank not downsize its balance sheets to the pre-crisis level and composition. A central bank can sell securities only if it owns them in the first place.

New Ways of Implementing Conventional Monetary Policy

The increased size of central bank balance sheets resulting from the asset purchase programs carried out during and after the 2007–09 financial crisis also raises potential

challenges for the implementation of conventional monetary policy through raising or lowering the central bank's policy interest rate. Enlarged asset holdings mean an enlarged quantity of central bank liabilities outstanding. Because little occurred during the crisis to increase the public's demand for currency, the counterpart of the large increase in assets held by these central banks was mostly an increase in the reserves they provided to banks. Further, because banks' deposits did not increase in any extraordinary way either, the great bulk of this increase in reserves consisted of excess reserves.

The danger potentially created by having such a huge volume of excess reserves outstanding is that once the economy begins to expand banks are therefore free to extend credit and create deposits in what would be almost unlimited amounts. To prevent them from doing so by traditional means, the central bank would have to shrink its volume of outstanding reserves – by selling assets – back to the level at which reserves became sufficiently scarce to raise market interest rates to the level needed to restrain economic activity, and with it potential inflationary pressures. One question raised by such a prospect is whether the assets that the central bank had accumulated in response to the crisis (mortgage-backed securities, for example) would have a ready market to permit sales in the required volume. A further question is whether, as the central bank sold off these assets in sufficient volume to enable it to raise its policy interest rate, these sales would so depress the prices of the remaining assets on its balance sheet as to create large losses (see Section Potential Risks from Large-Scale Asset Purchases: Portfolio Losses? above).

Most central banks regularly pay interest on banks' holdings of excess reserves, however. (In the United States the Federal Reserve System received legal authority to do so starting in November 2008.) With interest paid on excess reserves, the central bank does not need to reduce the quantity of reserves it supplies in order to raise short-term interest rates. It can simply raise the rate at which it pays banks to hold excess reserves – thereby raising the effective floor on market interest rates, since no bank would ordinarily lend to a customer at a lower interest rate than it would receive from holding risk-free reserves with the central bank. Paying interest on excess reserves therefore in effect severs the traditional connection between the quantity of reserves supplied and the interest rate at which reserves are exchanged for other assets, and hence market interest rates more generally. Once the economic and market effects of the 2007–09 crisis are in the past, central banks may choose to sell part or even all of the large volumes of assets that they purchased, but there is no need for them to do so merely in order to raise their policy interest rates. Indeed, over time it is possible that conventional open market operations may become much less relevant to the actual conduct of monetary policy.

Macroprudential Concerns

In seeking to understand the origins of the financial crisis of 2007–09, which proved so costly to so many economies, economists and policymakers have focused not just on the lax lending standards and inadequate supervision applied to many lending institutions (especially in the United States) but also on the extended period of low interest rates early in that decade, which apparently led many institutions to take on risks that in the event they proved unable to sustain. The result, in most of the high-income advanced economies, has been a new emphasis on financial regulation and also a new awareness of the extended trade-offs associated with monetary policy.

Financial regulation has traditionally focused on the soundness of individual institutions. By contrast, the new emphasis on macroprudential stability focuses on the systemic risk arising from the interconnectedness of financial institutions, in that one institution's assets are another's liabilities so that the lending institution is ultimately no stronger than the borrower. In the wake of the crisis, the United States enacted the Dodd–Frank Act of 2010, which established a new Financial Stability Oversight Council specifically charged with responsibility for such systemic concerns, and also implemented a wide range of new regulations on financial institutions as well as procedures for prompt government intervention in the event of threatened failure. The European Union began the process of unifying its member countries' banking systems, importantly including proposals for a uniform set of procedures for resolving bank failures. At the same time, countries around the world moved to designate specific institutions as 'systemically important,' thereby subjecting them to new layers of reporting and regulation. Also, under the rubric of the Basel Committee, central banks moved to raise banks' capital requirements as well as to impose new restrictions on banks' leverage based on each bank's total balance sheet (in both cases scheduled to take effect in 2018.)

With short-term interest rates at or near zero for more than half a decade following the crisis, in many of the large high-income economies, concerns over a potential repetition of the experience that led up to the crisis have also played a major role in the ongoing discussion. The fear is that institutions seeking to earn at least some positive return on their assets will increasingly turn to either longer-maturity holdings or holdings more exposed to default and other risk than is normal – or appropriate – for their amount of capital and exposure to volatility of their liabilities. The result has been growing awareness of a new form of monetary policy trade-off: between keeping the central bank's policy interest rate at the level that best achieves policymakers' macroeconomic objectives (under the postcrisis circumstances, as low as possible so as to stimulate economic activity in the face of lingering unused resources) and putting interest rates at a level consistent with the ordinary conduct of financial institutions' business in a way not exposed to excess risk (presumably much higher) (Goodfriend, 2002; Hanson et al., 2011; Friedman and Kuttner, 2011; Stein, 2013).

Abstract

This article starts with a section that emphasizes the importance of cultural factors influencing psychological aspects of money. General issues of 'what money can buy' are discussed including effects of money on family formation and disruption. The next sections address attitudes toward money and psychological consequences of merely thinking about money. The section 'handling money' reviews topics such as consumption, saving, and investing money, as well as evading taxes and donating money. Correlates of financial behavior are discussed. The final section focuses on issues of poverty and discusses the impact of scarce financial resources on well-being and social relations.

Introduction

As a major tool for exchanging goods and services, money plays a crucial role in economic and social life. It serves as a legal tender, unit for calculation, and allows keeping values over time. Tied to these economic functions, money has a large influence on human experience and behavior, delimiting consumer options, life styles, access to education, and even chances on the marriage market. Societies differ considerably regarding the distribution of income among their members and in the extent to which individual economic resources determine access to cultural goods such as education and health care. But individual differences in income almost invariably provide a major indicator of social inequalities (*see* Justice: Social Psychological Perspectives). Being one of the multiple markers of social stratification, money carries social prestige and may affect social relations as well as people's self-concept, experience, cognitions, and social behavior not only due to its economic function but also through the symbolic value attached to it. Thus, from a psychological perspective, money is much more than a neutral unit of account that the *homo economicus* strives to maximize, but has symbolic power that influences thinking, experiences, and behavior.

Despite the trend to increasing globalization that is particularly evident in international finances and the increasing importance of stock holdings among private investors in many nations, societies still differ beyond their financial systems in cultural norms and collective rationale, which shape attitudes toward money. Collective experiences with money can affect whole nations, as evident in the fear of inflation in Germany that followed the experiences after World War I, and recent and current economic crises that affect individuals as well as whole economies alike. This points to the importance of socialization not only for attitudes toward money but also for expectations concerning the larger economic system.

Furthermore, cultural norms and experiences with money guide the display of one's financial resources in public. People frequently discuss general financial issues such as prices and the tax system. However, in many cultures – except for materialistic cultures such as many cultures in South Asia – personal financial assets are mostly considered a very private issue, which is not discussed even with family members or friends. This lack of openness may serve to prevent social envy in the case of personal affluence and to help protecting one's social image if personal resources are scarce. Interestingly, other social symbols such as clothing and expensive cars allow to undermine this social norm, indicating that the social norm of avoiding talking about money only holds on an abstract level of finances but not on a level of concrete products.

Given the likely importance of cultural factors, available research on psychological aspects of money and finances suffers from a focus on Western systems. Furthermore, psychologists have paid surprisingly little attention to money as research topic (for an overview, see Furnham and Argyle, 1998) leaving this domain largely to sociologists and economists. Only recently, research in social and consumer psychology started to investigate the psychological consequences of money. Drawing on relevant research from different disciplines, this contribution first addresses the significance of money for personal well-being and social relations. Next, we turn to beliefs and values connected with money, and discuss the cognitive and behavioral effects of merely thinking about money. Thereafter, we address issues of handling money looking at correlates and predictors of spending, saving, and donating money, as well as evading taxes. In a final section, selected research on effects of poverty is summarized.

What Money Can Buy: The Personal and Social Significance of Money

Although folk wisdom claims that money does not make happy, findings point to an overall low, but significantly positive relationship between income and well-being (within-nation correlations range about between $r = .15$ and $r = .20$, Diener and Seligman, 2004). Not surprisingly, the prediction of happiness from economic resources improves if other indicators of wealth besides income are considered. Pointing to the importance of social comparison processes, relative income is more important than its absolute level because people define

themselves as wealthy or poor in comparison to others. In countries with high poverty rates and extreme income differences like India or Brazil, the relation between happiness and income is substantially stronger. Across 55 nations, the correlation between income and happiness reaches about $r = .50$ (Diener et al., 1995). Finally, increases in income during prosperous periods have a positive influence on citizens' well-being, whereas income losses during depression periods have the opposite effect. However, effects of changes in income on changes in satisfaction do not seem to last long. People adapt to higher as well as lower levels of income (Easterlin, 2003).

Much attention has been paid to the significance of money in family formation and family life (White and Rogers, 2000). Economic assets play a considerable role in marriage decisions, not only among women, who have traditionally been assumed to consider their partner's bread-winning potential, but also among men. Men's earning and employment have consistently been found to increase the likelihood of marriage, and even women's increasing participation in labor force does not seem to render male income less important. Furthermore, the income of men and women – in particular the difference in income between husbands and wives – affect the division of household labor between marital partners beyond time restrictions due to their employment. There is more sharing of household tasks between spouses if wives contribute more to family income (Coltrane, 2000). Economic resources also affect family relations. Conflict about financial affairs seems to be among the most important sources of discord in partnerships, and family violence has often been linked to the lack of financial resources. As to divorce, findings demonstrate a positive contribution of men's earnings to marital stability (e.g., Hoffman and Duncan, 1995). Benefits from women's higher earnings are less clear, because the stabilizing effect may be counteracted by women's higher economic independence that contributes to greater hazards of divorce ('independence effect'). However, the independence effect is relatively weak and may be restricted to marriages that are unlucky at the first place (Sayer and Bianchi, 2000; Oppenheimer, 1997). Furthermore, causality between women's income and marital quality/stability may be bidirectional: Marital discord was found not only to be affected by women's earnings but also to instigate women's higher labor force participation, which causes higher earnings (White and Rogers, 2000).

Attitudes toward Money

Attitudes toward money may be understood within a larger system of values that has been broadly distinguished as materialistic or postmaterialistic. Materialism is associated with greed for money which means that people strive for accumulating money beyond what is needed for survival, often at the expense of happiness (Dittmar, 2010; Kasser and Ahuvia, 2002). Based on Maslow's hierarchy of values, Inglehart (1977) claims that materialistic needs, related to stable economic resources and physical security, are basic and foregrounded in one's value system if they are not sufficiently fulfilled, specifically – coined in a socialization hypothesis – if they have been lacking during childhood and adolescence. Accordingly, situations that remind one of insecurity, such as awareness of death, increase materialism and conspicuous consumption (Arndt et al., 2004; Kasser and Sheldon, 2000). On the other hand, postmaterialistic values including political participation, freedom of speech, and self-realization will develop primarily if materialistic needs are satisfied. In line with these assumptions, research has shown that materialistic values are less foregrounded among the well educated and those with higher income, and particularly that post-materialistic values became increasing preferred among younger generations.

Interestingly, although greed and materialism may function to fulfill security needs on the level of the individual, they contribute to financial crises and thus financial insecurity on a global level: Materialistic orientations, short-dated bonuses for financial managers, and the greed of many investment bankers, who – often exceeding criminal thresholds – developed more and more innovative financial products that have been partly responsible for recent financial crises (Lenz et al., 2010). Here, money may function like a drug, such as consumption of cocaine or sexual activity; the prospect of profit activates the nucleus accumbens (i.e., the 'pleasure center' in the brain) and causes release of dopamine (Lea and Webley, 2006), which may be a sustaining factor for greed.

On a symbolical level, it is remarkable that money is associated with ambivalent characteristics and paradoxical meanings. Money is associated with positive values like security, independence, freedom, prestige, and possessions as well as with negative associations like anxiety, anger, greed, envy, conflict, and the 'pain of paying.' People who own much money are likely to be seen as hard working, successful, and even beneficent. But they are also at risk of being regarded as superior, selfish, capitalistic, and hostile. Given these complexities, research has focused much on understanding the basic structure of attitudes toward money.

Several different questionnaires have been constructed and psychometrically examined in order to investigate the fundamental dimensions underlying money attitudes (for an overview, see Furnham and Argyle, 1998). For example, the Money Attitude Scale (Yamauchi and Templer, 1982) differentiates between the factors power/prestige, retention time, distrust, quality and anxiety, whereas the Money Beliefs and Behavior Scale (Furnham, 1984) measures six factors: obsession, power/spending, retention, security/conservative, inadequate, and effort/ability. The short version of the Money Ethic Scale (Tang, 1995) summarizes three factors: success, budget, and evil. Materialism can be assessed with the Richins and Dawson's (1992) 18-item Material Values Scale. All different approaches to the measurement of money attitudes illustrate that the attitude structure is rather complex and multidimensional with clearly differentiable factors reflecting the ambivalence of money. Some of those factors are linked to clinical traits, such as anxiety or obsession, whereas others are related to the retention factor, such as saving and investing money. Other factors, such as power, prestige, and spending, show that money can also be a means to influence and impress others.

Affected by parental income, education, social class, beliefs, parenting practices, and money habits, money attitudes are formed early in childhood and remain fairly consistent throughout one's life. Empirical studies show that high-income people tend to think that money is less evil and rather reflects

one's achievement. Participants scoring high in protestant ethic are more likely to budget money properly and tend to see money as evil and representing power. High leisure-oriented individuals see money more frequently as good, representing achievement and power/freedom. In contrast to students with credit cards, those without are more likely to score higher on money attitudes of obsession and retention. Additionally, compared to normal consumers, compulsive spenders have been shown to have a relatively lower self-esteem, to believe more that one's self-esteem can be enhanced by money, and to be more convinced that money solves problems.

There are also attitudes toward banknotes and coins as the actual currency. Bruner and Goodman (1947) demonstrated the influence of subjective values and objective needs on the perception of currencies by asking rich and poor 10-year-old children to match circles of light corresponded to a range of coins. The results illustrate that the size of socially valued objects, such as coins, are judged larger than neutral objects, such as gray discs. Moreover, the greater the value of a coin, the more biased the estimation. This overestimation effect is stronger for poor than for rich children.

Thinking about Money

Recently, research in social psychology started to investigate what happens when people merely think about money. It has been found that such 'money priming' affects cognitions, emotions, and behavior. It has been shown, for instance, that priming with the idea of money changes cognitive processes (Hansen et al., 2013); mere reminders of money, such as pictures of money or thinking about the concept of money, trigger abstract (versus concrete) mental representations and an abstract style of thinking. For instance, participants who are primed with money represent actions more in terms of their abstract goals instead of their concrete means, they perceive the world in fewer and broader (instead of more and narrower) categories, and they are relatively quicker in identifying global pictures ('the forest') and relatively slower in identifying local details ('the trees'). This has also consequences for judgments and behavior; for instance, money primes cause a focus on central (instead of peripheral) aspects when evaluating objects. Furthermore, thinking about money also increases self-control (Boucher and Kofos, 2012), which is related to abstract thinking. Importantly, these effects only emerge when money is seen as a resource, so that the idea of money can prime security and personal strength. For people who associate money with the 'pain of paying' or with loss, reminders of money cause more concrete and detailed-oriented thinking styles.

Money priming has effects on social behavior, as well. For instance, it has been demonstrated that participants primed with the concept of money show a reduced tendency to request help with a difficult task (Vohs et al., 2006). Compared to participants of a control group, money-primed participants are also more reluctant to help other people. Additionally, money priming causes a preference to play and work alone, and increases the tendency to put more physical distance between oneself and a new acquaintance. These effects have been interpreted as result of money reminders signaling independence and self-sufficiency (Vohs et al., 2008); since money usually is associated with strength, it reminds one that people (including oneself) may have plenty of resources. Therefore, merely thinking about money causes the impression that other people and oneself need only few social resources.

Reminders of money also function as a pain buffer and affect emotions. For instance, thinking about money leads to experiencing less social distress and physical pain (Zhou et al., 2009). Although social support is the most important psychological factor that alleviates social distress and physical pain, reminders of money also function as pain buffer (Zhou and Gao, 2008). Conversely, social exclusion and monetary loss result in increased pain awareness. Additionally, research has demonstrated that anticipation of pain heightens the desire for social support as well as the desire for money.

Handling Money

Saving, Spending, and Investing Money

The decision to save money or to spend it for consumption is partly based on rational economic considerations. However, saving is also a socially accepted goal, formed during socialization and by norms of the social environment. Predicting people's saving behavior, economists focus on factors such as the increase of income, which leads to an overproportional increase of savings; social comparisons with other people, which influence habits of consumption and saving; and saving behavior as postponing consumption in order to guarantee a constant level of lifelong consumption (for an overview, see Webley and Nyhus, 2008). The framing approach of the 'behavioral life cycling' hypothesis by Shefrin and Thaler (1988) stresses the importance of individual self-control, self-imposed rules, and precommitments for explaining saving. Different forms of money, such as regular income, assets, or windfall profits, are subjectively categorized and assigned to different 'mental accounts.' The propensity to save all or part of an income is assumed to depend on which mental account the income is referred to.

Katona (1975) emphasizes the importance of differentiating between people's ability to consume or save and their willingness to do so. He has pointed out that people's beliefs about economic issues mediate the amount of money they save. People's consuming or saving behavior is based on expectations regarding the future development of the economic situation. The Index of Consumer Sentiment (Katona, 1975) predicts turning points in business cycles and expresses changes in optimism–pessimism about the financial future. It has been found that total saving increases when people become more uncertain and worried about the future. One-third of household saving in the United States is explained by the precautionary motive, in particular with regard to health and retirement considerations. Because saved money is often used as protection against economic risks, risk-averse individuals tend to have lower debts and save more money than risk-taking individuals.

Empirical studies (e.g., Furnham, 1985; Lunt and Livingstone, 1991; Traut-Mattausch and Jonas, 2011) show that age is linearly related to saving (the older the higher the savings), and that education has a curvilinear relation to saving (the most and least educated people save less, whereby the

more educated invest more of their money instead of saving it). Savers are more optimistic about economic circumstances and believe in personal control over finances, whereas nonsavers think of themselves more as victims of external events. However, they also seem to blame themselves more when things go wrong. Savers get more social support from friends and relatives than nonsavers and thus more information about how to handle finances. Savers show more consistent shopping habits, such as going to a few favorite shops, whereas nonsavers tend more to shop around.

Psychological research on financial investments in stock markets focuses on investigating the heuristics that people may apply when deciding how to invest their money (for overviews, see Gärling et al., 2009). Since financial decisions are highly influenced by the context in which price information is presented, salience and attention effects play a prominent role in financial decision making. For example, selective causal attributions provided by the media have a significant influence on investment decisions in financial markets (Andreassen, 1987); by explaining recent changes in stock prices with good news after prices rise and with bad news after prices fall, reporters tend to focus on the sets of facts that suggest that change should have happened and to omit the set of facts that suggest it should not have occurred. Such attributions foster expectations that changes will either persist or regress to previous price levels. This can mislead investors and result in wrong decisions in turn.

Tax Compliance and Evasion

About 20–30% of taxpayers in Western industrial nations do not declare their income completely. Approximately 10–20% of tax is illegally evaded. The majority of people think that their tax burden is too high and that they pay more taxes than other people and even more than those with a comparable income. The lack of transparency of the tax system and people's lack of knowledge about tax issues increase distortions in perception systematically (for overviews, see Jonas et al., 1999; Kirchler, 2007).

The economic approach suggests a very rational behavior of paying and evading taxes, which is only influenced by the benefits and costs associated with tax evasion, such as the subjectively perceived probability of detection, penalty rates, amount of income, and level of marginal tax rate (for an overview, see Andreoni et al., 1998). However, tax evasion is not only a matter of rational calculation and utility maximization but also of psychological variables such as an individual's willingness to evade or comply (*see* Social Dilemmas, Psychology of). Tax evasion is higher the more people experience money and profits in particular as an indicator of success and the more they perceive opportunities to do so. Negative attitudes toward the government, toward the fairness of the society's resource allocation, toward the legislation, and toward the spending behavior of political actors are also important in influencing tax evasion. Furthermore, tax evasion is lower the more important moral norms and religious values for a person and the higher his or her integration in the society. Finally, tax fairness, which is judged based on the comparison of tax burden and the government's provision of public goods as well as the tax burden of other taxpayers, is also an important predictor for tax evasion.

Donating Money

On the one hand, people are willing to take illegal actions to save money by evading taxes but, on the other hand, they voluntarily give money away by donating it to charities (*see* Altruism and Prosocial Behavior, Sociology of). Numbers of the Charities Aid Foundation show for Great Britain that more than two-thirds of the inhabitants donate money for charitable causes. However, the relationship between income and donations is quite low (only about $r = .13$; Furnham and Argyle, 1998). Considering the characteristics of people who donate money, it is found that people between the age of 50 and 65 years give the most; women give more money than men and are also more actively involved in volunteering. Married people give about 20–40% more than singles with a comparable income. Having children leads to an increased willingness to donate (about 50% more than people without children). People who are religious give about three times more than people to whom religion is not important. Concerning contextual factors, more money is given if the request comes from a physically attractive person, a similar person, or an expert. More money is also given in reciprocal relationships and to one's own group. Touching the potential donors and eye contact are effective strategies for raising donations. Furthermore, modeling and conformity have been shown to be crucial factors. Additionally, donating and spending money on other people have been shown to increase happiness; spending more of one's income on others than on oneself is associated with greater happiness, and participants who were randomly assigned to spend money on others experienced greater happiness than those assigned to spend money on themselves (Dunn et al., 2008).

When Money Runs Short: Perspectives on Poverty

In the past decades, issues of poverty have increasingly become addressed by social and developmental psychologists. Relevant research dates back to the 1930s when Jahoda et al. (1975, original 1938) introduced the ethnographic approach in studying a whole community that was hit by unemployment due to plant closing. Showing that different 'reaction types' (e.g., 'unbroken,' 'in despair') emerged as styles of coping with the increasingly desperate situation, early findings inspired later stress and coping research. Addressing family adaptations to economic loss, Elder (1974) showed that the families' adaptive reactions along with parents' stress during the Great Depression increased the likelihood of conflict and tension within families and shaped children's short- and long-term developments.

Present research focuses much on relative income poverty, defined by national poverty lines or by a per capita income of less than 50% of the average income. Different from former static approaches, more recent studies consider the duration of poverty and suggest, for instance, that stable poverty is experienced by only a small minority of children in the United States while a large share lives at least 2 years in poverty. In general, findings show that long-term poverty has more negative effects on well-being and children's behavior than short-term deprivation, but the latter is often detrimental, too.

Regarding effects of poverty, research pays increasing attention to children who have been pointed out as an important risk group of poverty in many countries, especially if living with a single parent, having two or more siblings, or belonging to ethnic minorities (e.g., Seccombe, 2000). Most studies report deleterious effects of poverty on both children's and adults' well-being and health, including lower life expectancy, higher infant mortality, and more acute and chronic health problems. Disadvantages often begin during pregnancy leading to low birth weight and undernourishment, thus increasing the risk for serious illness. In explaining these findings, impaired health among the poor has been linked to limited access to medical or prenatal care, to less healthy lifestyles, nutritional deficiencies, and low levels of education or literacy, making it difficult to use health services or follow health instructions. High levels of emotional stress have also been shown to negatively affect the immune system.

Furthermore, children living in poverty have more socio-emotional and behavior problems, have more difficulties in peer relationships, and do poorly in school. Much of these effects can be linked to parental stress, which results from the economic pressure they face and which spills over into the parent–child relationship leading to less nurturing, more authoritarian, and more inconsistent, harsh physical discipline. Hence, impaired parenting is important in mediating negative effects of income loss on children. On the other hand, individual and family resources (e.g., emotional stability and a harmonious marriage) may buffer the consequences of income loss for family life and children's development. Increased social support from family and friends has also been shown to reduce the stress and violence experienced by poor families, and to improve self-esteem. High rates of poverty in the neighborhood increase the likelihood of children's externalizing problems even beyond individual family income. Given the spatial segregation of poor families, problems arising from the lack of family and community resources are likely to cumulate.

Finally, it should be noted that running up debts is often used to compensate a lack of money. Despite the risk of serious financial problems due to long-term obligations, only few studies in psychology address such issues. Lea and Webley (1995) report that debtors have less money management facilities than nondebtors, rate their ability at money management lower, and think in shorter time horizons without considering long-term consequences. Debt counseling has become an important task in social services provided to the poor.

Conclusion and Outlook

From a psychological perspective, it is obvious that money is much more than just an economic exchange good. Although money is an important resource that affects many domains in life, much of its significance seems to derive from its symbolic value and from psychological processes, such as social comparison processes, or attitudes toward money, which are complex and often ambivalent. Similarly, determinants of handling money often go beyond economic rationale. Recent research includes more genuinely psychological perspectives (such as effects of money on cognition and social behavior) in studying the significance of money in people's life. Although we could not cover all topics that are related to money (for instance, for the psychology of incentives and motivation, *see* Pay, Compensation, and Performance, Psychology of and Work Motivation), the summarized topics demonstrate that the psychology of money and finances is a rich field in which research efforts are worthwhile. Further subjects related to money such as economic and financial policy, state indebtedness, ethics and moral issues when handling money, or the cultural history of money are interesting and – applied to psychology – provide a broad spectrum of promising avenues for future research.

Abstract

From premodern societies to the present, money has facilitated the trade of goods, services, and persons. With the rise of the modern nation-state came attempts to affirm national identity through money and to standardize monetary currencies so the state could pay for its wars. These political-economy explanations, however, obscured the other forms and functions that money has taken (and continues to take) in society. Even when money does not appear to take on heterogeneous forms of legal tender, it is accounted for and earmarked by different groups as if it were a multitude of entities. By studying the variation in what money looks like, how it is used, and how its meanings vary, sociological studies capture the cultural codes and multiple identities that constitute money and the marketplace.

What is money and why do sociologists study it? What forms has money taken over time, and how have the social meanings of money affected the purposes to which it has been put? Sociologists argue that the form that money takes depends on the societies producing it. The size, color, symbols, emotional salience, and restrictions on money do not arise out of a technical feasibility assessment but rather from the meaningful engagements of people, institutions, and their polity over how to exchange the rights to a good, how to create restricted versus generalized processes for transferring goods and services, and how to accumulate value that can be deployed in the future. The more that an object (or a virtual entity) fulfills these three functions – (1) enabling *the rights to* goods and services be transferred from one party to another, (2) legitimizing the general use of an exchange medium between a variety of parties or sites, and (3) facilitating value storage for later deployment – the more money-like it is (Zelizer, 2001). An exchange medium that does not fulfill all three of these criteria may nonetheless be money, just less fully so. (see Maurer, 2006 on the anthropology of money.)

Sociologists studying the degree to which an entity functions as money and the varieties of forms it takes draw from the lessons of history, ethnography, interviews, experiments, and surveys. We will begin with history to document just how many varieties of money have existed along with the social, political, and cultural situations that brought these monies into being. These studies help us understand that what we take as money, as value, and as a sensible way to engage in economic transactions could have been structured otherwise – and might still.

The Shift from Premodern to Modern Money

In premodern times, when people purchased slaves in Monomotapa in the Gulf of Guinea, they used cotton cloth as currency and referred to these swaths of cloth as 'piece[s] of India' (Braudel, 1981: p. 442). Not only cloth but also rocks, corral, nails, and furs served to store value and to facilitate the transfer of the rights to use objects or services. In the Trobriand Islands that Bronislaw Malinowski studied, women used different forms of currency than men did for different kinds of trades.

In the West, money itself reflected the social differentiations of class and status in society. Writing about money in the fifteenth to the eighteenth centuries, historian Fernand Braudel demonstrated how different categories of people were matched to different categories of money: "[E]very metal played its part: gold, reserved for princes, large merchants (even the Church); silver for ordinary transactions; copper naturally for the smallest. Copper was the 'black' money of people of small means and the poor. Mixed with a little silver it blackened quickly and deserved its name" (Braudel, 1981: p. 458). This use of money as a means of communicating social identity was not new. In a study of how money was used in Roman society between 200 BCE and 200 CE, Michael Crawford recalls how a person's relationship with money affected his dignity and reputation. As a result, Tiberius intervened in the dispute between the moneylenders and members of the upper classes in order to preserve their social status and to maintain the social order. Crawford writes:

> [I]n Rome, on the only known occasion on which money was supplied at public demand, it was supplied not for economic reasons, but, as we might expect, in order to preserve social status. In A.D. 33 the moneylenders of Rome, accused of irregularities, tried to turn the tables on their accusers and attempted to call in all their debts. The debtors were threatened with the necessity of selling off their land on a rapidly falling market to the evident profit of the usurers. But Tiberius intervened with an interest-free loan of 100 000 000 sesterces to those whose *dignitas* and *fama* were threatened…. On occasions of what appear to have been general currency shortages in 63, 49 and 44 BC no comparable intervention took place. (Crawford, 1970: p. 46)

Money functioned as a communicative instrument of social status and as a social mechanism for stability. In this instance, the social status of a particular category of individuals (not society's economic well-being) was threatened and therefore warranted an intervention in the money market. Had a different category of individuals been threatened by the moneylenders, the informal rules about how money should be used, against whom an economic threat could be made, and from whom the rule's enforcement would come would have differed.

Just as different categories of persons are matched with different categories of money, so too are different categories of money matched with varying rules of use. Crawford notes that some coins that held more economic value were nonetheless less valuable by virtue of the image on the coin. The Roman historian Arrian wrote that the coin bearing the image of Nero held more economic value than the one bearing the image of Trajan; however, the Nero coin was considered morally rotten, but the Trajan one fine. In other words, money was more than a means to an end; it was an end in itself, encompassing a set of value judgments. Money carried images and meanings that ought not be defiled. Indeed, Tiberius considered it a capital offense for a coin bearing the image of Augustus to be taken into a brothel or lavatory precisely because some types of money must be protected from defilement or moral pollution (see Crawford, 1970: p. 47).

With the rise of the modern nation-state, the variations in money diminished. The United States just after the Civil War, for example, faced both a practical and a symbolic problem. Before the Civil War, states and substate institutions issued their own currencies and scripts. With more than 5000 varieties of money in the United States, the polity seemed anything but united (Zelizer, 1994). The debts amassed during the Civil War generated a practical problem: with incommensurable currencies, how could the central governing institution pay its debts? And the struggles over unity exacerbated a symbolic problem: how do people's daily transactions remind them that they belong not simply to a state or to a regional body (such as the former Confederacy) but rather to a national community?

Political scientist Eric Helleiner uses an 1863 letter from S.M. Clark, the chief clerk of the US Treasury, addressed to Secretary Salmon Chase, in order to illustrate how the producers of currency intended to disseminate nationalist images through the circulation of money in the marketplace. The letter reads:

> [The money] would tend to teach the masses the prominent periods in our nation's history. The laboring man who should receive every Saturday night, a copy of 'Surrender of Burgoyne' for his weekly wages, would soon inquire who General Burgoyne was, and to whom he surrendered. This curiosity would be aroused and he would learn the facts from a fellow laborer or from his employer. The same would be true of other National pictures, and in time many would be taught leading incidents in our country's history, so that they would soon be familiar to those who would never read them in books, teaching them history and imbuing them with a National feeling. (Helleiner, 1998: p. 1412)

In other words, because money is widely circulated voluntarily by people who happen to use the market for procuring their needs, the state does not have to force a sense of national feeling. The national culture would cohere by virtue of consumption and economic exchange. As individuals engage in their routines and move through their daily rounds, they encounter monies and the images carried thereon. In this way, it is easy to understand why Fernand Braudel referred to money as one of the elementary 'structures of everyday life' (Helleiner, 1998: p. 1413).

Money is such an elementary form of everyday life that it is often taken for granted, and in its taken-for-grantedness, it is able to constitute meaning structures that influence the course of social action. Sociologists Bruce Carruthers and Sarah Babb (1996) use the historical case of money after the Civil War in the United States to demonstrate the extent to which the implicit expectations people have about money and its uses gets challenged when the medium of exchange itself becomes ambiguous and unsettled. The expenses of the Civil War were so great that the national government had to abandon the gold standard for fiat money. A variety of monies presented themselves: "national bank notes, state bank notes, greenbacks, currency convertible into specie, and specie coin" (Carruthers and Babb, 1996: p. 1557). Two camps – the bullionists (advocates of 'hard money') and the greenbackers (advocates of 'soft money') – emerged to contest the form that money should take in the United States. For the former, money had an intrinsic value, and its holders were honest Christians (not pagan shape-shifters). For the latter, money was a democratic creation subject to democratic control. Both sides argued that the type of money the state issued spoke to the underlying character and identity of the nation. As money speaks for character and identity, it moves beyond its economic function: "If money served only an economic purpose, it is unlikely that it would have been traditionally organized largely along national lines…. National currencies, and money more generally, need to be examined not just as an economic phenomenon but also in terms of their geographic, political, social and cultural dynamics" (Gilbert and Helleiner, 1999: pp. 1–2).

Simone Polillo continues the theme of identity, character, and money as he examines how financial elites in the United States (*c.* 1800–1913) and Italy (*c.* 1860–1913) have shaped collective identities in order to control new financial instruments. He identifies a binary between the conservatives and the wildcats, with the former maintaining barriers to credit for those lacking it and the latter generating new financial instruments and engendering new financial actors to enter the field. The financial instruments varied by their exclusivity (restrictions on who could possess them) and by the degree of control those possessing the instrument had.

The increase in the types of financial instruments reflected a proliferation of monies and corresponding practices: from hedge funds to exclusive credit cards; from relationship banking to mortgage backed securities. Each type of financial instrument entered into specific circuits of exchange, infused with symbols of membership and relationship categories.

> Much like the men of early-twentieth-century America analyzed by Viviana Zelizer (1994), who earmarked a significant portion of their earnings to spend it on rituals of sociability with other men (such as drinking together), financial elites earmark the most prestigious financial instruments to "spend" them in financial interactions with other financial elites, in the activity of trading that allows them to be at the center of vibrant financial markets. (Polillo, 2013: p. 7)

Polillo's findings reject the notion of money as fungible, because the financial instruments are effective to the extent that they are not fungible; moreover, the experience of Michael Milken's junk bond debacle illustrates the consequences of mismatching categories of money with inappropriate categories of practice.

The theme of money and national identity, most strongly linked in Polillo's analysis of Italy, also plays out in France. There, Helleiner notes "the growing use of national currency among the rural poor of France … as one part of a broader transformation that transformed 'peasants into Frenchmen' in the late nineteenth century. In his words, the new standardized national currency became "a universal language that all understood and all now wanted to speak" (quoted in Helleiner, 1998: p. 1415). In other words, the currency served as a great leveler, dulling rural–urban distinctions and making more salient the money individuals used as an indication of the nation to which each belonged.

Helleiner notes that currencies are utilized in religious-like interactions as people place their trust (an act of faith) and declare their devotion to a particular currency form. Adam Muller, a conservative Prussian writing in the early nineteenth century,

> believed that "the state's duty is to awaken national pride, the feeling of 'oneness' with the national state in the economic sphere" … A national currency was seen as a key tool in this project.… But this bond was not in terms of the issues of imagery, communication, the community of fate, or sovereignty.… Rather, it was at a more emotional level. (Helleiner, 1998: p. 1427)

The importance of iconography and the meanings of money do not disappear with the increasing differentiation of economic life or with the growing integration of modern economies. In his introduction to *The Year of the Euro* (2006), Robert Fishman examines the struggles over national identity in 2002 over the rise of a single European currency:

> The scenes of euro enthusiasts lining up beside automatic teller machines to withdraw new euro banknotes shortly after midnight on the changeover date, the confusion and petty disputes over currency conversion in some commercial establishments, and indeed all the many stories and experiences constituting the year of the euro stand as an enormous collective … experience spanning twelve European countries. (Fishman, 2006: p. 8)

The political project of national identity and of supranational organization relies on the "iconography … the values, themes, and concepts represented by artistic motifs [on the money] … [assist] in the construction of a European identity" (Hymans, 2006: p. 15). The nation-state tries to increase their legitimacy by using the currency to signal their embrace of values in tune with the 'spirit of the times' (Hymans, 2004: p. 6). Likewise, Nigel Dodd (1994) uses the symbols on money and reactions to their proposed alteration as evidence of the ongoing national identity work that money facilitates.

The European Central Bank remains a site for research in Carlo Tognato's (2012) investigations of money as a symbolic medium. Central bankers contest currencies and their associated territories as sacred or profane, granting monies character roles in a moral drama. Ministers of finance in euro member countries use religious imagery when talking about the order that the euro engenders and to warn against the chaos other currencies might unleash. Tognato identifies a range of ritual practices, public prayers, and cultural codes that constitute the macroeconomy of the European Union. Likewise, Bill Maurer (2002) identifies the religious underpinnings of financial derivatives.

Modern money and the cultural codes they depend on operate in discussions of taxation as well as discussions about consumer spending. Recent work on symbolic interaction identifies how groups of people in the southern United States use narratives about taxation to engage in boundary work (Kidder and Martin, 2012) – differentiating themselves as the exploited versus the exploiters, as creating (making) versus destroying (taking). Indeed, talk about taxes resembles what Wherry (2008) identifies in talk about consumer purchases: there are narratives that enable people to engage in boundary work, affirming those who are near to or far from a societal ideal. These discussions lead us to discussions of household finance, where we now turn.

Household Monies, Household Finance

Economic sociologists along with behavioral economists and psychologists have studied what money means and how households manage it. These different disciplines find that people do not behave as if money is fungible when arranging their household budgets. Zelizer contrasts her approach to earmarking (what she calls relational accounting) from the focus of psychologists as an individual's process of partitioning and evaluating budget categories:

> The distinction between individual and relational accounting is more than rhetorical: in the first view we might expect a given person's array of special monies to display a lot of stability and to vary considerably among persons as a function of life history; in the second, we might expect otherwise disparate people who are closely connected to have similar arrays of special monies. Those expectations differ significantly. However, because life histories and social relations intertwine, we should expect difficulty, at times, in distinguishing sharply between both types of accounting. (Zelizer, 2012: p. 160)

It is the way that individuals come together to form relationships and the ritual practices they engage in that matter crucially for how they engage in accounting. Zelizer's historical studies point to legal tender stored in a cookie tin that acquired a nickname and got allocated to specific budget categories. Money earned by a child got allocated differently from money earned by the female head of a two-parent heterosexual household. More recent studies acknowledge that people sometimes store money in different envelopes or utilize multiple bank accounts. In other words, the notion that money is just a means to facilitate market exchanges has been challenged by the regular practice of 'primitivizing' money – restricting its use by virtue of the identity of who earned it, the social relationships they are managing, and the purposes to which it will be put.

We can see the different approach that sociologists take to partitioning money, when compared with psychologists, in the example of the Christmas Savings Club. Psychologists study these clubs as self-control and commitment devices for individuals who cannot, otherwise, resist temptations to spend

rather than save. These savings clubs usually do not pay interest on the deposits, so from the point of view of a savvy budget manager, it would make more sense to put one's money into an instrument that allows profit generation. We can therefore look at the lost opportunity to profit as the cost of self-control.

Some economic sociologists tell a different story that complements this story of self-control. Viviana Zelizer reminds us that many working class women used these savings clubs in the early to mid-1900s. These clubs enabled these women to guard their holiday monies from other household members who might have compelled early expenditure. This was especially the case with their husbands. Zelizer writes:

> Indeed, the Christmas money was often reserved for domestic necessities such as a washing machine or a daughter's new coat…. the segregated Christmas money spared them from what was often considered the humiliating need to extract gift money from their wage-earning husbands. Thus, not only individual self-control but also negotiated household relations accounted for at least some of the Christmas clubs' great success in the United States. (Zelizer, 2012: p. 160)

The Christmas Savings Club taps into an existing ritual and set of practices that have become formalized. If it were not Christmas or another ritual well enough regarded, the club would not have the same power in keeping the money of wives off limits to their husbands. Christmas and its associated meanings probably helped these women challenge their husband's authority without threatening the relational roles of their husbands as the heads of their households. For love of ritual and the social relationships sustained thereby, people mark and manage their money.

Viviana Zelizer treats as different species of money the earmarks and nicknames given to budgeting categories. She uses cultural codes about family and gender and the variation in these codes for working-class women (compared with upper-class women) to explain what kinds of budgeting categories and practices households practiced at the turn of the twentieth century. The names granted to money varied along the lines of "allowance, pin money, 'egg money,' 'butter money,' spending money, pocket money, gift, or 'dole'" (Zelizer, 1989: p. 344). Following monetary practices enabled Zelizer to understand intrahousehold relations and interclass differentiations. Money itself served as a means for cultural communication.

Margarita Mooney (2003) and others have extended these insights to immigrant remittances. Households do not manage remittances simply according to what the needs of household members are but rather according to the identity of the person sending the monies home. If a household received remittances from a female household member (especially if that person is the mother), the monies tended to be earmarked for school fees, school uniforms, groceries, and clothes. By contrast, if a husband sent home earnings, they often earmarked the spending for larger, more expensive items (e.g., appliances, automobiles, home improvements). Treating money as if it is fungible and devoid of social meanings follows the fiction of a modern currency freed from its premodern functions. (For the social meanings of money in Africa, Asia, and Latin America, see Singh, 2013.)

Money in Theory

While Emile Durkheim had little to say about money, his nephew Marcel Mauss offered a cultural approach to money that took into account the interaction partners and other background conditions that make money effective as a medium of exchange. In *The Gift* ([1950] 2000), Mauss argued that an individual's gift is vested with her spirit, and this inalienable quality of the gift compels the recipient to reciprocate in kind. These objects being exchanged are attractive not because of the money value (price) but rather because the individuals involved are moral agents responding to moral stimuli. Objects used as money *enabled these moral claims to be affirmed* by the givers and recipients of gifts. These insights about the role of money in the exchange of gifts, as well as the implications of money for constituting the category of gift (rather than a repayment), have been taken up in Pierre Bourdieu's *Outline of a Theory of Practice* (1977). Bourdieu, however, focuses on the timing of the exchange than on money per se.

Karl Marx described money as a common denominator, a 'radical leveler' that "does away with all distinctions associated with traditional social relations" (Marx, 1974: p. 32). In *Structures of Everyday Life*, Fernand Braudel proffers a Marxist understanding of money as detrimental to intimate social relationships; the emergence of money brought "[s]harp variations in prices of essential foodstuffs; incomprehensible relationships in which man no longer recognized either himself, his customs or his ancient values" (Braudel, 1981: p. 436). Lamentably, labor became alienated from laborers and the individual's work became commodified, just as the worker herself or himself became 'a thing.'

In *The Philosophy of Money*, Georg Simmel notes that money is free to move across social sites without regard for social class, caste, or tribe. According to Helleiner, Marx and Simmel (2004 [1907]) "implied that, through its ability to reduce everything in the nation to a common 'language,' a national currency enabled citizens not just to communicate economically but also to think in a similar way and to situate themselves in a common fashion within the national community" (Helleiner, 1998: pp. 1417–1418).

Talcott Parsons ([1951] 1966) posits that money is indeed a language, a communication system, and that the economy is a means for society to adapt to its environment. And in Parsons and Smelser's *Economy and Society* ([1956] 2005) they provide a functionalist account of budgeting. Jens Beckert revisits this account in his discussion of the multiple functions of money and budgeting:

> Through spending on consumption, the social system 'household' fulfills institutionalized demands to live according to a certain lifestyle. Expenditure levels are determined by a culturally defined basket of goods that determines the 'cultural survival' (Parsons and Smelser, 1956: p. 221) of the household. Beyond that, expenditures for entertainment, leisure, and vacations are given a function for intra-family conflict management and, with that, status symbols assume an integrative function by positioning the household in relation to other households and thus symbolizing membership in a group. (Beckert, 2006: p. 171)

Household budgeting is both a positional and relational act, but the goal is not only to gain status but also to affirm

solidarity with a group; it is to rally around a totem. And these totems and their associated imaginings of what the future should hold affect budgeting decisions.

In *The Working Class and the Standards of Living* (1913), Maurice Halbwachs adopted Durkheim's theory of collective representations to explain the budgeting practices of families. Combining data from the Imperial Office of Statistics with that from the Union of Metal Workers, Halbwachs discovered that a future image (a representation) collectively held within a group affected (1) how families classified the categories in their budgets, (2) what percentage of their wage workers paid into each category, and (3) how budget categories were prioritized. Halbwachs did not argue against the concept of fungibility, as Zelizer (1994, 2010) does, yet he attends to collective representations (what Zelizer calls cultural codes).

Conclusion

Studying money facilitates nuanced understandings of social life. People establish, affirm, and contest national and regional identities. People erect boundaries between self and others, insiders and outsiders, but in doing so, they short-circuit purely arithmetical forms of evaluation. It is not useful for policy makers to hone in so-called bad decisions while ignoring the meaningful rituals and the overarching meanings that render strategies of economic action salient for the situation at hand. It is counterproductive to flatten money as a technology of exchange rather than a meaningful instrument that groups use to communicate who they are and what they hold sacred.

Money: Anthropological Aspects

Abstract

From its traditional concern with 'primitive' moneys and definitional quandaries over the nature of money in small-scale and nonmarket societies, anthropology more recently has considered money's meanings in multiple, overlapping spatial, cultural, and temporal milieu, as well as the pragmatics of money – what it does and how it signifies, rather than what it is or what it signifies. Early twenty-first century business interests in divesting the state of its monopoly over the legitimate means of exchange open new frontiers for the anthropology of money and value.

Early ethnologists were stunned by the range of things that seemed to be used as currency, from shells to braids of tobacco to giant, nearly immovable stones. Over the course of the twentieth century, several anthropological positions on money crystallized: (1) that 'primitive' is to be distinguished from 'modern' money in that the former is special purpose, employed only for exchanges involving certain things or transactions, or in specific, bounded domains of social life (say, marriages, death, or religious rituals), while the latter is general purpose, able to be employed for all manner of things and transactions, and across domains; (2) that special purpose moneys can be used for each of the Aristotelian 'functions' of money, different objects serving as means of exchange, method of payment, store of value, and measure of value or unit of account; (3) that, therefore, modern money is a universal or general equivalent, after Marx, and that it became the measuring rod against which all things and transactions can be evaluated; and (4) the colonial experience worldwide was one of the supplanting of local, special purpose moneys by modern, general purpose money that thereby; (5) deracinated and flattened objects' and relationships' meanings, purposes, and modes of evaluation by replacing them with one mode of value tied to the market logic of supply, demand, and price. By the 1980s, anthropology in most quarters had explicitly or implicitly essentially adopted an Aristotelian–Marxian–Simmelian perspective on money: as fulfilling the classic functions identified by Aristotle, as commensurating incommensurabilities and serving as a general equivalent as discussed by Marx, and as eroding 'social' or familial connection with the flat wash of anonymous money as argued by Simmel.

In the late twentieth century, however, money itself underwent several important transformations. First, many of the core European countries adopted a single currency, the Euro. The breakup of the Soviet Union and fragmentation of the Eastern Bloc countries into their constituent units led to the creation of new currencies, as well as the extension of the Eurozone eastward to new regions. Several countries adopted the US dollar as their official currency; others are informally dollarized; while the rise of China led commentators and everyday folk alike to question the US dollar's status as the global reserve and standard of value. Aside from their political and economic aspects, these interrelated phenomena spotlighted the relationship between money and sovereignty, money not just as a state project but as a symbol of the nation. Anthropologists explored this symbolism in a unifying Europe (Peebles, 2011) as well as in a former socialist world adapting to a market-based global economic order (Truitt, 2013; Lemon, 1998).

Second, informal flows of money from the global North to the global South reconfigured social and political relationships while creating the material conditions for transnationally distributed extended families. Coming into the twenty-first century, South–South remittance flows have become significant, reconfiguring political, familial, and financial relationships. Anthropological studies of remittances emphasized money's role in creating and sundering relations while serving as a means of communicative action (Hernandez and Coutin, 2006; Pedersen, 2013) and creating new collective identities. This work echoed earlier research suggesting that money mediates different temporal cycles, short-term exchanges in a marketplace vs longer term, durable and transgenerational relationships (Parry and Bloch, 1989).

Third, global financialization – the rise of finance as an industry in its own right rather than in the service of raising capital for productive enterprise – together with the use of market principles for governance, led anthropologists to look at the speculative aspects of money and credit. Marxist stories of abstraction, commensuration, and money as fiction excavated from informants' stories around the world led anthropologists to explore the spectral, fantastic, and magical properties of money. If Bohannan's interlocutors in the early twentieth century were struck by the capacity of modern money to equilibrate values and violate bounded spheres of exchange, the Comaroffs' were more spell struck, according to money magical powers wielded by the undead or witches (Bohannan, 1959; Comaroff and Comaroff, 1999). These themes were familiar to anthropologists whose earlier work had recorded peasants' explanation of the reproduction of money in terms of the intercession of the gods or devils (Taussig, 1980). Yet attention to credit and finance raises a particularly anthropological question: How to demarcate what counts as 'money' in ways anthropologists once did regarding so-called primitive currencies (Maurer, 2012).

Money and sovereignty, money and kinship, money and spheres of exchange, money and abstraction, spirits and speculation – these were the stuff of the anthropology of money at the end of the twentieth century. Anthropologists had come a long way from the old days of simply cataloging

the great diversity of objects used as media of exchange or stores of value.

Several empirical realizations and theoretical shifts are beginning to make more complex these themes and to suggest others. First, anthropologists, as (for the most part) subjects of capitalist, modern societies, came to the study of money with their own folk theories of economics and value in place. Disabusing ourselves of the idea that practical reason is acultural (Sahlins, 1978) proved easier than culturally situating the idea of money as always a commodity. Anthropologists have been as surprised as their informants to discover that money is a collective illusion, that its representational logics often fail. Is it a stand-in for 'real value,' or is it 'really valuable' in and of itself? (Foster, 1999). Hart usefully reminded the field as early as 1986 that money is always both a token and a commodity, but this lesson, and his equally significant revelation that money is above all a recording device, a kind of externalized memory, are still sometimes forgotten (Hart, 1986, 2001).

Guyer's important revision of Bohannan situated his spheres of exchange as part of a broader colonial and slave economy of an Atlantic Africa with ties to Birmingham and Nantes (where manillas, the brass bracelets serving as a currency of the slave trade, were actually manufactured) and beyond (Guyer, 2004). Bohannan had argued that 'conveyances' within one sphere of exchange are morally neutral but 'conversions' across the spheres are morally fraught, with people wanting to convert up into higher prestige spheres but loathe to convert down (Bohannan, 1959). Putting transactions in a broader historical and geographical context Guyer found that one could make a conveyance in another region, returning with new items from another sphere to convert up closer to home. In other words, Guyer finds conversion, not conveyance, to be a generalized phenomenon, and one inextricably bound with position in a set of sometimes intersecting hierarchies and geographies. For Guyer, this introduces the necessity of placing rank and its associated numerical relationships of ordinality at the center.

Guyer's move, in turn, required a more complex engagement with number itself. Numbers are not just a priori logical givens and do more than count things. There are different metaphors, embodiments, and physical or metaphysical reference to numbers. Rather than seeing number, like (the myth of) modern money, as abstracting and commensurating, tout court (Crump, 1978), recognition of rank requires an expansion of the analytical vocabulary for different kinds of numbers and styles of quantification and enumeration (Verran, 2001). This is becoming a fruitful area for the anthropological study of money (Pickles, 2013) but has to battle the headwinds of analysis of 'neoliberalism' and financialization that still insist on viewing the world in terms of the unfolding of one logic of capitalist abstraction, and one valence of quantification (Appadurai, 2011).

Guyer herself takes up the variety of conversions among different orders of value and geographies in order to query the contemporary world of multiple currencies (Guyer, 2012). Most, she observes, are 'soft,' that is, they do not function as a store of value or a reserve, but as a means of exchange. In economies of soft currencies, it is the money supply and not its ultimate value per se that matters, and that keeps exchanges going. One does not hold money, fetishizing its value, but instead tries to keep it moving and, crucially, to convert up. It is this potential for conversions that preoccupies people. The borders between domains and positions, the temporal dimensions of exchanging 'up,' and a variety of units of account and measurement thus map out a program for empirical investigation.

Guyer's program emphasizes creativity, dynamism, and pragmatic action. Another line of thinking in the anthropology of money focuses on money's materiality. One might assume that this work is therefore more static or less historical. This is not the case. Anthropological linguists developing a material semiotics have found in money a useful demonstration of some of their theoretical stances. Keane and Kockelman, in different ways, emphasize money's materiality as a communicative medium. Keane argued that when money is material, that very materiality underdetermines money's semiotic content (does it signify because of the marks inscribed on it? does it signify because of its qualities of being heavy, smooth, shiny, brittle?) (Keane, 2001). This indeterminacy allows money to remain an open signifier (Foster, 1999; Rutherford, 2001). Kockelman likens money to infrastructure – that which carries value across time, space, and language, a communicative channel subject to being redirected, skimmed from, or destroyed (Kockelman, 2010). Similar work along these lines draws attention to the polysemy of numbers on banknotes (Strassler, 2009), counterfeit notes (Chu, 2010), or redenominated actual (Dzokoto et al., 2010) or spiritual (Kwon, 2007) moneys. These studies shift anthropological attention from what money signifies, to how it does so.

There is much merit in bringing together these new strands of anthropological thinking on money. From the shift away from ethnological obsession with simply cataloging the stuff of money, to the opening-up of the spheres of exchange paradigm, to the reconsideration of money and number, money and commensuration, and money and abstraction, anthropologists can begin to examine the complex monetary ecologies and repertoires in which, even in a postneoliberal world, people make and do money with each other. The task, however, remains difficult: anthropologists are like most other moderns in accepting the separation, for example, of quality from quantity, and the purification of these as distinct and irreconcilable domains (Callon and Law, 2005; Latour, 1993). Anthropologists also take money, along with number, as necessarily capitalist forms of abstraction. Here, the work of economic sociologists (Zelizer, 1994) remains useful in pointing out the zones and practices in which people simply do not use money to equilibrate or deracinate but rather to make distinctions and relations.

Anthropologists also kept alive the intellectual tradition that saw money as a form of credit and as the state's monopoly over finality in payment, as guarantor of the clearance, and settlement of exchanges. Economist Wray, who has been a leading voice for the recovery of state and credit theories of money, writes:

> Theories of money became increasingly simplistic and silly [after the 1970s] with the rise of New Classical, Real Business Cycle and even New Keynesian approaches to macroeconomics. Serious monetary

> research was left to the fringe in economics (Post-Keynesians, Institutionalists, Political Economists, Social Economists), or to other disciplines such as Sociology or Anthropology.
> (Wray and Bell, 2004: 3)

This alternative tradition in monetary theory has become important in the aftermath of the global financial crisis that began in 2008. As with prior large-scale economic crisis, this one fed a reconsideration of money itself. As in the 1970s, activists and others rediscovered time- and community-based moneys of account like Time Banking and alternative currencies (Maurer, 2005; North, 2007). Others, however, drew from metallist traditions, becoming latter-day gold bugs as well as advocates of new currency experiments based on monetarist assumptions and the idea that value derives from scarcity (Maurer et al., 2013). Some academics rediscovered chartalism or state theories of money, as well as credit theories of money (Graeber, 2011) that see money as alternately the product of the state's enforcement of the use of its coupon to pay taxes, or as a chain of debts the ultimate arbiter and enforcer of which is the state. Others, particularly mainstream economists, either held onto monetarism or awakened the Keynes that had been lurking inside them all along (Krugman, 2013).

Governments, too, have been experimenting with new forms of exchange. As already noted, several countries dollarized, yet some of these same countries have been exploring various experiments in 'social economy' and 'solidary economy' (Nelms, 2013), a reaction against the G8 club of powerful countries setting global economic policies and agendas, as well as an assertion of the new power of some countries of the global South like Brazil. This took place as the Euro itself faltered: Greece and Cyprus exemplified the challenges of maintaining a currency union in the absence of unified fiscal policy.

The infrastructures of money are changing. Money in the core capitalist countries is increasingly – for the wealthy, at least – dematerialized. Electronic payments have reduced cash use in some countries. Some governments and nonprofits have an explicitly anticash agenda (Bjorklund Larsen, 2012). Their thinking assumes that cash's anonymity makes it the preferred vehicle for criminal activity and tax evasion. Digitizing transactions simultaneously institutes an electronic record, which can be audited, monitored, and tracked. Often put in terms of efficiency and convenience, electronic money systems at the same time frequently function through publicly traded, corporate infrastructures such as the payment card networks (Visa, MasterCard), which levy fees for transit.

Yet the digitization of cash also poses for anthropology and the study of money more generally the age-old question of what money in fact is, how people use it and what they use it for. In a sense, the digitization of money represents a return to the recognition of money as a memory device, as a means of recording credits and debts. What distance is there, really, between the cuneiform ledgers of ancient Sumer and the electronic transactional databases recording many of the world's payments in the early twenty-first century? There is of course the obvious distinction that the ancient database was a public one. But Hart for one has argued for new political options and vocabularies for a world of transactional data:

> Once we accept that money is a way of keeping track of complex social networks that we each generate, it could take a wide variety of forms compatible with both personal agency and collective forms of association at every level from the local to the global. It is up to us to build them.
> (2007: n.p.)

The early twenty-first century seems to be a new era of experimentation with and on money. Professionals from across the information and communications technology and the payments industry held large conferences to reimagine the future of money. Often there was a slippage in their discussions between the future of the transit of or infrastructures for state-issued money, and the future of money itself – its potential disintermediation from the state, and the introduction of a Hayekian world of privatized, denational currencies. A further slippage ensues when so-called money innovators waver between imagining these currencies as tokens or as commodities valuable in themselves because of some presumption of their scarcity.

Still, the increased circulation of private tokens harks back to the era before the consolidation of national currencies and, in the United States at least, the 'wildcat' banking period before state banks were regulated (Helleiner, 2003). If anything, innovations in money's transit and form are reopening a debate over the role of central banks in creating money and setting monetary policy and in the boundaries of regulatory authority over the means of payment and value transfer. The EU in the early 2000s issued several directives that tried to draw a fine line between infrastructures for value transfer and value storage, the latter seeming to invade the state's role as warranting the token at the top of the 'money pyramid' (see Wray and Bell, 2004: 12).

The historical irony is that as private industry experiments with infrastructures of value transfer and storage, and as populism on the left and right of the political spectrum contributes to the delegitimization of fractional reserve banking and central banks more generally (and this article is being written at the centenary of the US Federal Reserve system), central bankers have been busy rescuing the economies of the core capitalist nations. And a few anthropologists have been conducting fieldwork alongside them (Holmes, 2009).

From curatorial interests in the curiosities of primitive moneys, to debates over spheres of exchange and earmarking, anthropologists have more recently emphasized that money is representationally complex, more complex than a story of deracination and abstraction will allow. Its materiality matters, and it is not just a symbol (of state, of value, of social relations, or of power) but a practice. People's everyday interactions with money, especially outside the areas of the world dominated by reserve currencies whose value is more or less stable (though fragile), tend to emphasize its means of exchange modality, for there is no sense in hording a thing whose value may evaporate tomorrow. The view from this world of 'soft currencies' (Guyer, 2012) and of complex repertoires of money, number, value, and social relations may ultimately have more to say about the

involution and privatization of money in the early twenty-first century than that of the economists, monetarist, neoclassical, Keynesian, or otherwise.

Montague Grammar

Barbara H Partee, University of Massachusetts Amherst, Amherst, MA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Montague grammar is a theory of semantics and of its relation to syntax, developed by the logician Richard Montague and subsequently extended by linguists, philosophers, and logicians. Montague grammar had its roots in logic and the philosophy of language; it became influential in linguistics, and subsequently evolved into contemporary formal semantics. Enduring features of the theory have been a truth-conditional theory of meaning, a model-theoretic conception of semantics, and the methodological centrality of the Principle of Compositionality: "The meaning of a whole is a function of the meanings of its parts and their mode of syntactic combination."

Introduction

Montague grammar is a theory of semantics, and of the relation of semantics to syntax, originally developed by the logician Richard Montague (1930–71) and subsequently modified and extended by linguists, philosophers, and logicians. Classical Montague grammar had its roots in logic and the philosophy of language; it quickly became influential in linguistics, and linguists have played a large role in its evolution into contemporary formal semantics. The most constant features of the theory over time have been the focus on truth-conditional aspects of meaning, a model-theoretic conception of semantics, and the methodological centrality of the Principle of Compositionality: "The meaning of a whole is a function of the meanings of its parts and their mode of syntactic combination." This article presents an outline of the origins of Montague grammar, summarizes the basic principles of the classical form of the theory, and describes some more recent developments and interesting controversies.

Montague Grammar in Historical Context

Richard Montague was a logician and philosopher of language whose seminal works (1970a,b, 1973) founded the theory known after his death as Montague grammar. Montague had been a student of Alfred Tarski (1901–83), one of the pioneers, with Frege and Carnap, in the model-theoretic semantics of logic (Feferman and Feferman, 2004). As a logician, Montague built on that tradition and developed an intensional logic with a rich type theory and a possible worlds model-theoretic semantics, incorporating certain aspects of pragmatics, including the treatment of 'indexical' words and morphemes like 'I, you' and the present tense. In the late 1960s, Montague turned to the project of 'Universal Grammar,' which for him meant a theory of syntax and semantics encompassing both formal and natural languages.

Montague's idea that a natural language like English could be formally described using logicians' techniques was a radical one at the time. Most logicians believed that natural languages were not amenable to precise formalization, while most linguists doubted the appropriateness of logicians' approaches to the domain of natural language semantics.

Part of the context of Montague's work was the 'Ordinary Language' versus 'Formal Language' war among logicians and philosophers of language. The Ordinary Language philosophers were a new generation who rejected the formal approach of Russell, Carnap, and Tarski, urging closer attention to Ordinary Language and its use. Central figures were the late Wittgenstein, Strawson, Austin, and Ryle. In 'On Referring' (Strawson, 1950), Strawson wrote, "Neither Aristotelian nor Russellian rules give the exact logic of any expression of ordinary language; for ordinary language has no exact logic." Russell replied in 'Mr. Strawson on Referring' (Russell, 1957): "I may say, to begin with, that I am totally unable to see any validity whatever in any of Mr. Strawson's arguments." … "I agree, however, with Mr. Strawson's statement that ordinary language has no logic." Thus both sides in this 'war' (as well as Chomsky, as expressed in his reply to Bar-Hillel (Chomsky, 1955)) were in agreement that logical methods of formal language analysis did not apply to natural languages.

Also at the time of Montague's work, Chomskyan generative syntax was well established, and linguists were developing and debating approaches to semantics to fit into the enterprise of generative grammar, and questions on the relation of semantics to syntax had become central. The 'linguistic wars' between generative semantics (Lakoff, Ross, McCawley, Postal) and interpretive semantics (Jackendoff, with the support of Chomsky) were in full swing.

Montague rejected the premises of the 'Ordinary Language' versus 'Formal Language' war. His 'Universal Grammar' (Montague, 1970b) begins with the sentence, "There is in my opinion no important theoretical difference between natural languages and the artificial languages of logicians; indeed I consider it possible to comprehend the syntax and semantics of both kinds of languages with a single natural and mathematically precise theory" (p. 222). And while he was sympathetic to Chomsky's goals, he was not impressed with the results 'emanating from MIT,' remarking, "I fail to see any great interest in syntax except as a preliminary to semantics" (Montague, 1970b, p. 223).

In the earliest introductions of Montague's work to linguists, including Partee (1973, 1975) and Thomason's extended introduction to Montague (1974), it was argued that Montague's work offered the potential to accommodate

 http://dx.doi.org/10.1016/B978-0-08-097086-8.53022-0

some of the best aspects of both generative semantics and interpretive semantics, with some added advantages of its own.

Early attempts to integrate Montague grammar with transformational grammar (Partee, 1975) faced two kinds of obstacles. On the one hand, Montague's own syntax was quite unconstrained and in practice combined some systematic use of categorial grammar with some ad hoc extensions; it clearly needed overhaul for serious linguistic work. On the other hand, transformational grammars of the period could not be directly coupled with Montague's semantics because many of the posited transformations did not have uniform semantic effects, as Montague's theory required. Much of the subsequent diversity in approaches to formal semantics that incorporate features of Montague's theory reflect different responses to those problems.

Montague's work, and related work by the philosophers Michael Bennett, M.J. Cresswell, David Lewis, Terence Parsons, Robert Stalnaker, Richmond Thomason, and others, and by linguists such as Emmon Bach, Robin Cooper, David Dowty, E.L. Keenan, Lauri Karttunen, and Barbara Partee gained influence during the 1970s. Formal semantics became a mainstream approach to semantics within linguistics by the 1980s; major textbooks include Chierchia and McConnell-Ginet (1990), Dowty et al. (1981), Gamut (1991), and Heim and Kratzer (1998); a good 'lay introduction' is Bach (1989). See also Janssen (1981), Lewis (1970), and Partee (1976, 1997).

The Theory and the Substance of Montague Grammar: Central Principles

The paper of Montague's that had the most impact on linguists and on the subsequent development of formal semantics was "The proper treatment of quantification in ordinary English" ('PTQ') (Montague, 1973): short, but densely packed. 'Montague grammar' has often meant what Montague did in the fragment in PTQ and the extensions of PTQ by linguists and philosophers in the 1970s and 1980s with greater or lesser innovations. But it is the broader algebraic framework of 'UG' ('Universal Grammar,' Montague, 1970b) that constitutes Montague's theory of grammar. This section therefore begins with the basic principles laid out in UG, concentrating on the Principle of Compositionality, then continues with model-theoretic interpretation, type theory, and the 'method of fragments,' including some of the key features of the fragment in PTQ.

Universal Grammar: Syntax and Semantics as Algebras, Compositionality as Homomorphism

Montague's 'Universal Grammar' (Montague, 1970b) contains the most general statement of Montague's formal framework for the description of language. The central idea is that a grammar should be able to be cast in the following form: the syntax is an algebra, the semantics is an algebra, and there is a homomorphism mapping elements of the syntactic algebra onto elements of the semantic algebra. This very general definition leaves a great deal of freedom as to the nature of these algebras. In a logical language, the elements of the syntactic algebra can be the well-formed expressions. But for a natural language, ambiguity makes that impossible, since the homomorphism requirement means that each element of the syntactic algebra must be mapped onto a unique element of the semantic algebra. So for a natural language, the elements of the syntactic algebra are usually taken to be expressions together with disambiguating structural descriptions, typically trees of some sort.

The nature of the elements of the semantic algebra is also open to variation. They may be model-theoretic constructs, as in Montague's own work, Heim's 'file change potentials,' the extensional domains of first-order logic, hypothesized concepts, expressions in a 'language of thought,' or anything else, as long as they can be formalized in a suitable algebra. What is constrained is not the 'substance' of the semantics but properties of its structure and its relation to syntax.

It is the homomorphism requirement, which formalizes the compositionality requirement, that provides one of the most important constraints on UG in Montague's sense. The compositionality requirement, stated in the introductory paragraph, is almost uncontroversial when stated informally. But formalizing it requires an explicit theory of syntax (to specify what is meant by *parts* and *syntactic combination*), an explicit theory of semantics (*meanings*), and an explicit theory of the mapping from one to the other (*is a function of*).

Logicians typically specify the syntax of a formal language as a recursive definition; in that case the requirement of compositionality as homomorphism can be satisfied by giving the semantics in the form of a parallel recursive definition. The 'derivation trees' that correspond to the steps in applying a recursive definition become the elements of the syntactic and semantic algebras, and the homomorphism requirement says that each syntactic derivation must be mapped onto a unique semantic derivation.

The simplest linguistic examples take the elements of the syntactic algebra to be (sub)trees generated by a context-free grammar, and semantic interpretation to specify how the interpretation of a given subtree is computed from the interpretations of its immediate 'daughter' subtrees. Formal semanticists often work either with a 'monostratal grammar,' i.e., a grammar with a single level of syntax and no transformations (Generalized Phrase Structure Grammar (GPSG), Head-Driven Phrase Structure Grammar (HPSG), Lexical-Functional Grammar (LFG), Categorial Grammar, Tree-Adjoining Grammar (TAG)), or with a specified level of syntactic representation such as 'LF' (a syntactic level of 'logical form') in Chomskyan syntax.

Model Theory: Direct and Indirect Interpretation

Montague's 'Universal Grammar' presents formal frameworks for both 'direct' and 'indirect' semantic interpretation. The fragment of Montague, (1970a) illustrates the direct model-theoretic interpretation of natural language syntactic rules; direct model-theoretic interpretation of natural language is also found in some of the work of Cresswell, von Stechow, and Kratzer. 'Indirect' interpretation, illustrated in UG and PTQ and in the works of many others, proceeds via translation into an intermediate language, such as Montague's intensional logic. The translation process must then itself be compositional, meaning that the translation of

an expression must be a function of the translations of its parts, and the intermediate language must itself be given a compositional model-theoretic interpretation. The intermediate language is then, in principle, dispensable. Montague viewed the intermediate language as offering increased perspicuity in presentation but attached no theoretical importance to it; linguists tend to want evidence for or against the psychological reality of any posited level of 'semantic representation,' but strong evidence for or against such levels is still lacking.

Type Theory and Intensionality

Linguists before Montague had tried unsuccessfully to give a compositional semantics to natural language syntax, but their efforts were stymied in part by the mismatch between natural language syntax and first-order logic. The richness of Montague's logic, with several crucial features previously unfamiliar to linguists, was a crucial factor in the possibility of giving a compositional semantic interpretation to independently motivated syntactic structure.

Natural languages have many kinds of expressions: sentences, noun phrases, verb phrases, adjectives, adverbs of several sorts, prepositional phrases, and more. First-order logic has only three 'types' of expressions: formulas (analogous to sentences), terms (analogous to a subset of noun phrases), and predicates (analogous to nouns, adjectives, and verbs); this means that 'logical forms' for natural language sentences must often have structures very different from the structure of the given language. Montague's logic has a rich system of types built up by recursive rules from two simple types t and e corresponding to formulas and terms. One rule builds up 'functional types,' defining for any two types a and b the type <a,b> of functions from a-type things to b-type things. The other rule builds 'intensional types,' defining for any type a the type <s,a> of functions from possible worlds to things of type a. In order to follow Frege's insight that one can view function-argument application as the basic 'semantic glue' by which meanings are combined, Montague makes crucial use of the lambda calculus, first introduced by Church (1940), in order to explicitly define functions and work with function-argument application in compositional derivations. With his rich system of semantic types, Montague showed for the first time how one can interpret noun phrases like *every man*, *the man*, *a man* uniformly as semantic constituents, something impossible with the tools of first-order logic.

Intensionality is a key notion in the analysis of referential opacity. The construction exemplified in "Jones is seeking…" is *referentially opaque*, since the substitution of one coreferential expression for another in that context does not always preserve the truth value of the whole. It may be true that Jones is seeking the president and false that Jones is seeking Mary's father even though the president is Mary's father. Montague's intensional logic develops Frege's distinction between *sense* and *reference* and Carnap's distinction between *intension* and *extension*, to treat the phenomenon of referential opacity, pervasive in belief-sentences and other propositional attitude constructions.

Montague analyzed intensions as functions from possible worlds to corresponding extensions: propositions as functions from possible worlds to truth values, individual concepts as functions from possible worlds to individuals, properties as functions from possible worlds to sets. Montague proposed that not only propositional attitude verbs like *believe* create opaque contexts, but also transitive verbs like *seek* and *need*, modifiers like *former* and *alleged*, and prepositions like *about*. Montague's analysis of intensionality opened up new avenues of research as well as leading to interesting controversies and discussions of possible alternative ontological foundations for semantic theory.

The Method of Fragments: The PTQ Fragment

Each of Montague's three 'grammar' papers (Montague, 1970a,b, 1973) contains a 'fragment.' The term was introduced in 'English as a formal language' (Montague, 1970b), which begins:

> In the present paper I shall accordingly present a precise treatment, culminating in a theory of truth, of a formal language that I believe may be reasonably regarded as a fragment of ordinary English.
>
> Montague, 1974, p. 188

The 'method of fragments,' a methodological feature of Montague's work, is the writing of a complete syntax and semantics for a specified subset ('fragment') of a language, rather than writing rules for a single construction while making implicit assumptions about the rest of the grammar.

The fragment of PTQ, the best known of Montague's works, had a number of noteworthy features. One was the systematic correspondence between syntactic categories and semantic types, an appreciation of which led to a revival of interest in categorial grammar, where such a correspondence is built into the system of categories.

Another innovation was Montague's bottom-up syntax, combining concatenation and transformation-like operations in single recursive grammatical rules (modeled on the recursive rules of logicians' syntax), thus building well-formed expressions of all sorts of categories directly, rather than building an entire 'deep structure' top-down and then applying transformations bottom-up.

Montague's PTQ contained many other ideas that were new to linguists, some of which had antecedents in the work of other logicians and philosophers. We mention only a few here. The fragment illustrated the use of lambda-abstraction to generate phrasal conjunction directly, without the need for the semantically problematic syntactic transformation of 'Conjunction Reduction.' Montague introduced a version of Quine's treatment of relative clauses as 'sentential adjective phrases' derived from open sentences by lambda-abstraction, without any kind of 'deletion under identity.' Thus instead of deriving *The boy who loves Mary is happy* from the pair of sentences *The boy loves Mary* and *The boy is happy* by a transformational rule, Montague starts from an 'open' sentence like *He*$_3$ *loves Mary* and derives *who loves Mary* from that, lambda abstracting over the variable x_3, which interprets *he*$_3$, to interpret the relative clause as the property of being an individual who loves Mary. The relative clause is then combined with the noun *boy* very much as an adjective like *blond* would be. Montague also introduced the binding of

bound-variable pronouns by lambda operators rather than directly by quantifiers or by their antecedents, a move that has had major consequences for theories of anaphora. He used meaning postulates to distinguish entailments due to individual lexical items (e.g., that *seek* entails *try to find*) from entailments due to the semantics of a grammatical construction, e.g., that *A boy who loves Mary arrived* entails that *A boy arrived*, and laid the foundations for the strong 'lexicalist' tradition in formal semantics led by Dowty (1979).

Early Formal Pragmatics

The term pragmatics is due to Charles Morris (1938). Within semiotics, the general science of signs, Morris distinguished three branches: syntactics (now syntax), the study of "the formal relation of signs to one another"; semantics, the study of "the relations of signs to the objects to which the signs are applicable" (their designata); and pragmatics, the study of "the relations of signs to interpreters" (1938, p. 6). Semantics in the work of formal language philosophers such as Russell is pure semantics, and the need for attention to context dependence in interpretation was one of the concerns of the ordinary language philosophers. One of the first aspects of context dependence on which logicians made progress was tense, where Prior and Reichenbach were pioneers. And Montague was an important contributor to these developments. In "Pragmatics" (Montague, 1968) and "Pragmatics and intensional logic" (Montague, 1970c), he developed a higher order typed intensional logic that unified tense logic and modal logic, extending Prior's work and building on Church's work on intensional logic and type theory (Church, 1951), and more generally unified 'formal pragmatics' with intensional logic.

From Montague Grammar to Formal Semantics

Early Impact of Montague's Work on Linguistics

Before Montague, linguists took as the task of semantics the explication of ambiguity, semantic anomaly, and synonymy: the key questions were how many readings a sentence has, and which sentences share readings. But the individuation of 'readings' had always been problematic, so there was often crucial disagreement about data. The introduction of truth conditions as the basic semantic property of a sentence that a semantic theory should capture profoundly affected the adequacy criteria for semantics, and led to a great expansion of semantic research.

A methodological principle implicit in Chomskyan syntax in the 1960s, encouraged although not required by the Katz–Postal hypothesis that meaning is determined at deep structure (Katz and Postal, 1964), and carried to extremes in generative semantics, was the principle that sameness of meaning should be reflected in sameness of deep structure. But from the perspective of Montague grammar, sameness of meaning does not require identity at any syntactic level (cf Thomason, 1976): semantics is model-theoretic, not representational, not 'syntactic.'

With a semantics that made it possible to calculate compositionally whether two expressions have the same truth-conditional potential or not, many linguists concluded that there was no need to invent ever-more-abstract underlying structures in order to capture synonymy or sameness of truth conditions, and much of the motivation for that aspect of generative semantics disappeared. Its semantic goals could apparently be met, even exceeded, in a formal semantic approach, offering greater explicitness and compatible with more 'conservative' syntax. Thus the rise of Montague grammar was undoubtedly one factor in the decline of generative semantics and the fading away of the linguistic wars.

Details of Montague's analyses have in many cases been superseded, but in overall impact, PTQ was as profound for semantics as Chomsky's *Syntactic Structures* was for syntax. Emmon Bach (1989) summed up their cumulative innovations thus: Chomsky's thesis was that English can be described as a formal system; Montague's thesis was that English can be described as an *interpreted* formal system.

Montague's method of 'fragments' is no longer widely followed except in rule-based approaches to computational linguistics, where completeness is a necessity. Many aspects of Montague grammar have found fruitful application in computational semantics (see section 'Computational Semantics'), and many innovations (such as methods for working with underspecified representations rather than with large sets of meanings of ambiguous expressions) have in turn come from the computational semantics community.

Linguistics–Philosophy Interactions in the Development of Formal Semantics

At the time of Montague's work, there were already interactions between linguists and philosophers; Donald Davidson and Gilbert Harman, wanting to encourage more cooperation and understanding, and optimistic about generative semantics, organized a conference in 1969 that included the linguists Emmon Bach, Charles Fillmore, George Lakoff, James McCawley, and Barbara Partee, and the philosophers Donald Davidson, Peter Geach, Gilbert Harman, David Kaplan, W.V. Quine, J.F. Staal, and Bruce Vermazen. The conference resulted in the influential volume (Davidson and Harman, 1972), which also included the important papers (Kripke, 1972; Lewis, 1970; Montague, 1970c) and papers by others not at the conference. And in 1968, a first version of Terry Parsons' "A Semantics for English" (Parsons, 1972) was circulated, a number of linguists knew and discussed that work, as well as (Donnellan, 1966), and there was much interest among linguists in the puzzles of 'donkey pronouns' posed in Geach (1962). The philosophers Julius Moravcsik and Jaakko Hintikka, together with the polymath Patrick Suppes, organized a 1970 workshop of linguists and philosophers that included Montague's last paper. The linguist Edward Keenan was well versed in logic and philosophy; in addition to his own innovative work on semantics, syntax, and linguistic typology, he organized a conference in 1973 that led to the influential interdisciplinary volume (Keenan, 1975), in whose title the term 'Formal Semantics' made an early appearance. The philosopher Richmond Thomason edited Montague's works on 'formal philosophy' and included a long pedagogical introduction for linguists and philosophers (Thomason, 1974). The first collection of papers on Montague grammar (Partee, 1976) included papers by the philosophers David Lewis, Richmond Thomason, Michael Bennett, C.L. Hamblin, and M.J. Cresswell and by linguists Barbara Partee, Robert Rodman,

David Dowty, and Muffy Siegel, plus a paper co-authored by a linguist and a philosopher, Robin Cooper and Terence Parsons. Philosophers and linguists in Germany, Scandinavia, and in Amsterdam also did important work in Montague grammar starting in the 1970s.

In the 1970s and 1980s there were many interdisciplinary conferences and a significant number of collaborative works by linguists and philosophers or logicians: Barwise and Cooper, 1981; Bennett and Partee, 1972; Chierchia and Turner, 1988; Cresswell and von Stechow, 1982; Keenan and Stavi, 1986; and more.

Approaches to the Syntax–Semantics Interface

Montague had a very abstract theory of syntax (as an algebra), and some specific syntactic ideas; but in general his semantics was far more influential than his syntax. There have been many proposals for different ways to link Montague's semantics, or some variant of it, to different sorts of syntactic theories. Partee originally proposed ways to synthesize Montague grammar with Chomsky's transformational grammar (Partee, 1973, 1975). But the richness of Montague's semantics eliminates some of the motivation for transformations and lends itself to a monostratal syntax with a rich lexical component. Theories that have included a semantics influenced by Montague grammar include Extended Categorial Grammar, GPSG, HPSG, Heim's File Change Semantics, Dynamic Montague Grammar, and to some extent Kamp's Discourse Representation Theory and Asher and Lascarides' more recent Segmented Discourse Representation Theory. Starting with the work of Heim (1982), there has also been a rich tradition of theories using Chomskyan generative grammar with a syntactic level of logical form, using that as the syntactic input for compositional formal semantics.

The Naturalization of Formal Semantics

As formal semantics has developed from Montague grammar since the beginning of the 1970s, it has increasingly become a core part of mainstream theoretical linguistics, with continuing important contributions from logicians and philosophers. Areas of early research success tended to be in the 'logical' parts of language: quantification, anaphora, conjunction, tense, and aspect. Later work expanded the domains covered and the range of languages treated. An important development of the 1980s was the work of Kamp and Heim on Discourse Representation Theory and File Change Semantics. Their work led to changes in theories of indefinite noun phrases, quantification, and anaphora, and more generally led to the replacement of truth conditions by 'context change potential' as the core semantic property of sentences. Later work by Groenendijk and Stokhof gave an alternative perspective on the dynamic interaction of meaning and context (Groenendijk and Stokhof, 1990, 1991) with associated innovations in logic. Formal theories of topic-focus structure, interrogatives, presuppositions and implicatures, and many other aspects of natural language semantics and pragmatics have also been developed.

The basic model theory has been enriched by additional structure on the domain of entities, to model mass nouns and 'plural entities' (Link, 1998), and by widespread acceptance of events as basic entities. Kratzer and others have argued for a 'situation semantics' as a more fine-grained model structure, taking possible situations as parts of possible worlds. There is increasing attention to details of lexical semantics, and to interfaces of semantics with syntax, on one hand, and pragmatics on the other.

Further Developments and Controversies

Typology and Natural Language Metaphysics

The issue of "Natural Language Metaphysics" (Bach, 1986) is an important foundational area that connects cognitive issues with formal semantics and linguistic typology. What presuppositions concerning the constitution and structure of the world as humans conceive it are built into human languages, and how, and which are universal? These questions may concern both semantic structure and semantic content, from the semantic difference between nouns and verbs to the content of color terms or whether time is discrete or continuous. Their investigation may challenge the lines between semantic knowledge and other kinds of knowledge. Formal semantics, following the logical tradition, initially employed relatively 'austere' model structures; recent investigations, particularly into lexical semantics, are leading to richer model structures.

Formal semantics has increasingly expanded its scope to include work on a wide variety of languages, and in recent decades has made significant contributions to the study of linguistic universals and linguistic typology (Bach et al., 1995; Bittner, 1994; Keenan and Paperno, 2012; Matthewson, 2010; von Fintel and Matthewson, 2008). Typological investigations, especially but not only in the domains of quantification and of tense, aspect and mood, have included the distribution of nominal versus adverbial quantification, the semantics of languages that lack a determiner category, and the range of tense and aspect systems. Recent work on the formal semantics of sign languages has led to enriched perspectives on the semantics of demonstratives, variable binding, propositional attitudes, quotation, and other domains (Quer, 2005; Schlenker, 2011).

Computational Semantics

Until recently, there were few attempts to apply formal semantic methods to computational linguistic tasks, one interesting exception being the Rosetta project led by Jan Landsbergen at Philips Eindhoven in the 1980s (Rosetta, 1994). Recently, there have been advances in methods for making formal semantics computationally tractable, and interest in computational formal semantics has increased to the point that there are textbooks and courses in the field (Blackburn and Bos, 2003, 2005; Bunt and Muskens, 1999). A few companies have begun to offer computational linguistic products that use formal semantics and others are exploring the possibility of doing so. For some kinds of natural language processing problems, such as the solving of the kinds of logic puzzles found on the Graduate Record Exam, formal methods can offer important advantages and have been implemented (Lev et al., 2004). Connecting computational linguistics, psychology, and formal semantics, there is promising current research aimed at combining the best of statistical/probabilistic and formal approaches, exemplified by the

work of Joshua Tenenbaum's Computational Cognitive Science group at MIT (Tenenbaum et al., 2011).

Psycholinguistics and Formal Semantics and Pragmatics: Processing and Acquisition

Other recently expanding domains of research connect psycholinguistics and formal semantics, research that helps to strengthen both fields. The study of how children develop an understanding of sentences with quantifiers has a relatively long history (Crain, 2009; Philip, 1992; Smits et al., 2006). The study of real-time processing of language in both adults and children has expanded over recent decades to include attention to semantics and pragmatics as well as syntax, with particular interest in issues of compositionality, modularity, and the extent to which such pragmatic phenomena as implicatures interact with semantics (Chierchia et al., 2004; Frazier, 1999). A recent overview of work on the acquisition of semantics can be found in Crain and Thornton (2011).

Context Dependence and Formal Pragmatics

In subsequent work on Montague grammar and formal semantics, the treatment of context-dependent phenomena such as tenses, pronouns, demonstratives, and all sorts of indexicality has been a central concern. Other aspects of formal pragmatics such as the treatment of presupposition and focus sensitivity have been recognized as central to the study of meaning, so that 'formal semantics and pragmatics' has increasingly come to be seen as a single field, as described in Kadmon (2001) and as evidenced by the new online journal *Semantics and Pragmatics*; the aspects of pragmatics most closely connected to semantics are called 'near-side pragmatics' in the useful article by Korta and Perry (2008). The separation of pragmatics and semantics has been further challenged with arguments that the interpretation of pragmatic implicatures occurs interspersed with semantic interpretation (Chierchia, 2004).

Ongoing Debates within and around Formal Semantics

Some aspects of Montague's approach met with resistance or skepticism in the linguistics community, and some aspects were controversial among philosophers. We mention three foundational issues that distinguish Montague grammar, and formal semantics in general, from other approaches to semantics.

Many linguists have resisted the relevance of truth conditions and entailment relations to natural language semantics, and some still do. Some of the objections to truth conditions are countered by arguing that part of human semantic competence is the matching of sentences with their truth conditions relative to possible worlds (including fictional worlds), with no necessary reference to the 'actual world.' Entailment (sentence A *entails* sentence B if sentence B is true in every possible state of affairs in which sentence A is true) is a central semantic concern in logic, and remains so in formal semantics. Cognitive semanticists replace concern with logical entailment by concern with human inference; formal semanticists see the relation of entailment to actual human inference as indirect. But many semanticists agree about the importance of revising the formal logics invented by logicians to model the 'natural logic(s)' implicit in the semantics of natural languages.

Many linguists think of semantics in terms of a 'level of representation' of expressions analogous to a syntactic or phonological level. A representational view of semantics is quite congenial to the popular computational theory of mind. The contrasting model-theoretic view sees semantic interpretation relating expressions to elements of models (possibly mental models) defined in terms of constituents such as possible situations, entities, properties, truth values, etc.

The nonpsychologistic tradition of 'objective' (though abstract) meanings (Frege, Tarski, Carnap, Montague) contrasts with the psychologistic view of meanings 'in the head' (Fodor, Lakoff, Jackendoff, and all psychologists). Do expressions refer to objects or to concepts? Is semantics a branch of mathematics, or is it (as on the Chomskyan view of all of linguistics) a branch of psychology? Classical formal semanticists, who take the first disjunct in these choices, follow David Lewis in distinguishing semantics from knowledge of semantics, making semantic competence interestingly different from syntactic competence. More recent work in the philosophy of mind and of perception (Burge, 2003; Stalnaker, 1989) goes a long way toward reconciling the apparent tension between objective and mentalistic foundations for semantics by emphasizing how mental states depend in significant part on the environment: "Meanings are in the head like footprints are in the sand" (Stalnaker, 1989).

New Directions in Formal Semantics and Pragmatics

Many new directions have been mentioned in the preceding sections. Others include the emergence of game-theoretical semantics (Hintikka and Sandu, 1997) and a game-theoretical approach to integrated semantics and pragmatics (Benz et al., 2005). A number of researchers are exploring experimental and corpus-based methods for gaining new kinds of data for semantics as well as syntax (Krifka, 2011). There are beginnings of neurolinguistic research in formal semantics (Brennan and Pylkkänen, 2008) to complement the much older tradition of studying the neurolinguistic encoding of lexical meanings.

Of the key journals for the field, one, *Linguistics and Philosophy*, first published in 1977, maintains the collaborative links between those fields that marked the beginnings of Montague grammar. Another, *Natural Language Semantics*, first published in 1993, is more nearly centered within linguistics and includes greater concern with the syntax–semantics interface. A third, *The Journal of Logic, Language, and Information*, first published in 1992, reflects the split found in some European universities, where Chomskyan syntax is located in linguistics departments and formal semantics within philosophy or logic departments. And *Journal of Semantics*, which began in 1982, has recently reoriented itself to become a major venue for formal and experimental semantics. There is now also an important online open-access journal, *Semantics and Pragmatics*, first published in 2007, whose name reflects the increasing integration of those two subfields.

While this article has emphasized Montague grammar and formal semantics within linguistics, fruitful cross-fertilizations between linguistics and neighboring fields continue to strengthen and enrich the field now as they did at its beginnings.

Abstract

Monte Carlo simulation methods can be used to numerically evaluate expectations of functions of random variables (e.g., posterior moments of parameters of interest) for which no analytical expressions are available. They consist of generating random draws from the relevant distribution and replacing expectations by arithmetic means across such draws. Under appropriate technical conditions, the (statistical) accuracy of Monte Carlo estimates is inversely proportional to the number of draws. In cases where a sampling density is not available, which produces sufficiently accurate estimates, one will try to construct an auxiliary sampling density, which is called an importance function. The ratio between the integrand and the selected importance function defines the corresponding remainder function. The initial expectation is then estimated by the arithmetic mean of realizations of the remainder function under random draws from the importance function. An efficient importance function is one which closely resembles the initial integrand under an appropriate metric and, thereby, produces accurate Monte Carlo estimates under as few draws as possible. The article discusses several methods for constructing efficient importance functions at a sufficient level of generality.

General Principle

The term importance sampling (IS) designates a method designed to improve the numerical performance (or efficiency) of Monte Carlo (MC) simulation methods for the evaluation of analytically intractable integrals, generally expectations of functions of random variables. Early descriptions of the method can be found, e.g., in Kahn and Marshall (1953), Trotter and Tukey (1956), or in the commonly cited monograph of Hammersley and Handscomb (1964, Section 5.4). Examples of applications are the numerical evaluation of Bayesian posterior expectations of functions of parameters of interest – see, e.g., Kloek and van Dijk (1978) or Geweke (1989) – and that of a likelihood function in the presence of unobserved latent variables – see, e.g., Durbin and Koopman (1997) or Richard and Zhang (2000).

The general principle of IS can be outlined as follows. Consider a situation where one has to numerically evaluate an integral of the form

$$I = \int_D \phi(x)\mathrm{d}x \qquad [1]$$

where ϕ denotes a real function defined on $D \subset R^p$.

A case of special interest is that where ϕ takes the form of the product of a density function μ with support D and a function h whose expectation has to be evaluated on μ, say

$$I = E_\mu[h(x)] = \int_D h(x)\mu(x)\mathrm{d}x \qquad [2]$$

In the subsequent analysis, μ will be referred to as an 'initial' sampler, to be distinguished from the importance sampler introduced below.

In low-dimensional applications (say $p \leq 5$), one might consider using nonstochastic multivariate quadrature rules, as described, e.g., in Stroud and Secrest (1966) or in Golub and Welsch (1969). However, higher-dimensional applications require the use of MC simulation methods. The two most widely used methods are Monte Carlo Markov chain (MCMC) methods (see Markov Chain Monte Carlo Methods) and IS which is presented here.

IS requires the selection of a class of samplers, indexed by an auxiliary vector of parameters $a \in A$, say $M = \{m(x|a); a \in A\}$. While in some applications M might consist of a single sampler, it is generally advisable to select a class of samplers and then, within that class, a specific sampler under an appropriate 'efficiency' criterion. Selection of M and of a sampler within M are discussed further below, once the purpose of IS has been clarified. In the case of formula [2], it will often be the case that M consists of suitable parametric extensions of μ and, therefore, that μ itself belongs to M, i.e., that there exists $a_0 \in A$ such that $\mu(x) \equiv m(x|a_0)$ on D. While, as discussed further below, such a condition may be instrumental in the construction of M, it is by no means a requirement of the method.

For any given $a \in A$, the integral in formula [1] can be rewritten as

$$I = \int_D \left[\frac{\phi(x)}{m(x|a)}\right] m(x|a)\mathrm{d}x = E_m\left[\frac{\phi(x)}{m(x|a)}\right] \qquad [3]$$

In the case of formula [2], this expectation is often rewritten as

$$I = E_m[h(x)\omega(x;a)] \qquad [4]$$

where

$$\omega(x;a) = \frac{\mu(x)}{m(x|a)} \qquad [5]$$

denotes the weight function associated with the sampler m.

For any given $a \in A$, an MC IS estimate of I is then given by

$$\widehat{I}_S(a) = \frac{1}{S}\sum_{i=1}^{S}\frac{\phi(x)}{m(x|a)}\bigg|_{x=\tilde{x}_i(a)} \qquad [6]$$

where $\{\tilde{x}_i(a); \quad i: 1 \rightarrow S\}$ denotes a set of S identically independently distributed (hereafter i.i.d.) draws from the auxiliary sampler $m(x|a)$. If $m(x|a)$ is such that the sampling variance

$$\sigma^2(a) = \int_D \left[\frac{\phi(x)}{m(x|a)} - I\right]^2 m(x|a)\mathrm{d}x \qquad [7]$$

is finite, then a central limit theorem applies, whereby the random variable $\sqrt{S}(\widehat{I}_S(a) - I)$ converges in distribution towards a Normal with zero mean and variance $\sigma^2(a)$. Let $\widehat{\sigma}_S^2(a)$ denote the MC finite sample variance of the ratio ϕ/m in formula [6]. A numerical estimate of the variance of the estimator $\widehat{I}_S(a)$ is then given by $(1/S)\widehat{\sigma}_S^2(a)$. Note, therefore, that once a sampler has been selected, the numerical accuracy of the corresponding IS estimator of I, as measured by its MC standard deviation is of the order $S^{-1/2}$. Poor selection of a may require a prohibitively large MC sample size in order to achieve sufficient accuracy. Conditions for the finiteness of $\sigma^2(a)$ are discussed, e.g., in Geweke (1996) or Stern (1997). A sufficient condition is that $|\phi/m|$ be bounded above on D. Convergence in the absence of such a condition may be notoriously more difficult to verify.

If there exists $a_* \in A$ such that $\phi(x) = m(x|a_*)$ on D, then $\sigma^2(a_*) = 0$ and $\widehat{I}_S(a_*) = I, \quad \forall S \geq 1$. More generally, one would aim at selecting a value $\widehat{a}$ on A which minimizes the MC sampling variance $\sigma^2(a)$. Since, however, $\sigma^2(a)$ does not have an analytical expression and can only be numerically approximated, the actual choice of $\widehat{a}$ will often be based upon more heuristic considerations – some of which are discussed further below – aiming at constructing importance samplers which 'approximate' $\phi(x)$ on D. It should be noted that the term importance sampling emphasizes the fact that $m(x|a)$ is precisely meant to oversample in the 'important' parts of the domain D, i.e., those parts which contribute most to the value of integral I.

It is, however, useful to draw users' attention to a potentially misleading interpretation of this notion of region of importance. In practice, it is generally the case that large, possibly infinite, values of $\sigma^2(a)$ will not be generated by values of x in the region of importance (where most importance samplers are expected to perform well by design), but instead by values of x which can be very far away in the tails of $m(x|a)$ and which are, therefore, most unlikely to be ever drawn in a finite sample MC simulation. This situation can be particularly pernicious when D is unbounded. Earlier applications of IS to the computation of Bayesian posterior moments did occasionally suffer from such pathologies, especially in situations where non-informative prior distributions were used in combination with a (qualitatively) poorly identified model, see Statistical Identification and Estimability. (Note that in such cases, truncation of the support D of the posterior density may not be an acceptable solution, insofar as the moments of interest might be highly sensitive to such a truncation.) A classical example of nonexistence of $\sigma^2(a)$, which has been widely cited in the early Bayesian literature on IS, is that where ϕ^{-1} has polynomial tails (e.g., if μ in formula [2] takes the form of a Student-t density kernel) and one selects for M a class of Normal samplers. Nonexistence of $\sigma^2(a)$ may be particularly difficult to detect when it originates from such low-probability events. Indications of a potential problem are the empirical findings that the MC sampling variance of $\widehat{I}_S(a)$ does not decrease inversely proportionally to S or, relatedly, in the context of formula [4], that a few draws, often less than a handful, carry excessive relative weights. It is, therefore, absolutely critical to pay very close attention to estimates of the MC sampling variance of $\widehat{I}_S(a)$ and/or to the behavior of the weight function in eqn [4], at least in those cases where the existence of $\sigma^2(a)$ cannot be formally assessed.

Construction of Importance Samplers

Thus the two critical issues in the design of a successful IS implementation are: (a) the selection of an appropriate class M of auxiliary samplers; and (b) the selection within that class of an 'efficient' sampler, i.e., one for which the MC sampling variance $\sigma^2(a)$ is as small as possible. A number of truly innovative proposals to that effect are found in the recent econometric and statistical literature, though there remains a significant lack of generic principles for the construction of efficient importance samplers (one recent exception to this general statement is presented on its own in Section 3 below). As discussed further in the concluding remarks, this lack of generic principles is perceived by some as a significant impediment to routine use of IS. In the following some of the most useful proposals which have been offered in the late twentieth-century literature are briefly presented.

While Tierney and Kadane (1986) do not discuss IS per se, they propose an extension of the Laplace method of integration, as discussed, e.g., in De Bruijn (1958), to construct approximations for Bayesian posterior moments and marginal densities. The very same idea can be used to construct an importance sampler to approximate numerically the exact integrals. See Richard and Zhang (1998) for an application of this principle to a logit model with unobserved heterogeneity. Since, however, the Laplace method essentially serves to construct a local approximation around the mode of $\phi(x)$, it remains important to pay special attention to tail behavior in order to control for $\sigma^2(a)$, as discussed above.

Geweke (1989) pays attention to the minimization of the MC sampling variance $\sigma^2(a)$ within specific families of IS densities, typically multivariate Student-t densities and skewed generalizations thereof, labeled split-t densities. A problem with his approach, which is characteristic of any attempt at minimizing $\sigma^2(a)$, is that the latter depends upon integrals which have themselves to be numerically evaluated (a problem which will be addressed in Section 3 below). In the same paper Geweke also discusses more heuristic procedures for tailoring $m(x|a)$ in ways which proved quite successful in some Bayesian applications. It should also be noted that Geweke's article includes numerous references relative to MC simulation and numerical integration.

Evans (1991) develops adaptive methods which rely upon earlier draws of x to identify large values of the weight function defined in formula [5] and accordingly to modify the importance sampler. While such adaptive methods can occasionally

prove useful, they do suffer from the problem explained earlier, whereby values of x for which the weight function $\omega(x; a)$ is large are typically highly unlikely to be drawn.

Owen and Zhou (2000) discuss improvements of IS technique which are shown to work quite well in low-dimensional applications. One proposal consists of combining IS with the method of 'control variates' to produce an upper bound for the MC sampling variance. (The method of control variates uses knowledge of approximate integrals to I to reduce the MC sampling variance of $\widehat{I}_S(a)$. See Hammersley and Handscomb (1964) or Hendry (1984) for detailed descriptions of the control variate method.) Another extension consists of pooling several IS estimators in order to reduce MC sampling variances.

Durbin and Koopman (1997) apply IS to evaluate the likelihood function of non-Gaussian state space models. Their application is particularly interesting in that it consists of a fairly sophisticated and, in a sense, indirect application of IS in dimensions which are significantly larger than those of the applications discussed above. Let $p(y|\lambda,\theta)$ denote a non-Gaussian density for a vector y of observables, conditional on a vector λ of unobserved variables and a vector θ of unknown parameters. Let $v(\lambda|\theta)$ denote the density of λ given θ. Finally, let $g(y|\lambda,\theta)$ denote a Gaussian approximation to $p(y|\lambda,\theta)$. Under g one can use standard Kalman filter techniques, as discussed, e.g., in Harvey (1990), to compute a likelihood function $L_g(\theta)$ and, in parallel, a density $v_g(\lambda|y,\theta)$ for the latent variables. It is then trivial to show that the actual likelihood function.

$$L_p(\theta) = \int p(y|\lambda,\theta)v(\lambda|\theta)\mathrm{d}\lambda \qquad [8]$$

can be rewritten as

$$L_p(\theta) = L_g(\theta)\int \frac{p(y|\lambda,\theta)}{g(y|\lambda,\theta)}v_g(\lambda|y,\theta)\mathrm{d}\lambda \qquad [9]$$

The advantage of formula [9] over formula [8] is that it relies upon numerical integration to evaluate departures from the Gaussian likelihood L_g, rather than the likelihood itself. The density v_g in formula [9] plays exactly the role of an importance sampler. Durbin and Koopman (1997) then discuss the construction of the approximating Gaussian model in order to secure maximal numerical accuracy. The interest of that application is to show that the selection of an importance sampler can be approached indirectly via the construction of an operational approximation to a complex model.

Another sophisticated implementation of IS is found in Madras and Piccioni (1999) where the authors propose to provide greater flexibility in the choice of the class of samplers M, often a sticky problem in applications of IS, by allowing $m(x|a)$ to be the (implicit) equilibrium distribution associated with a Monte Carlo Markov chain simulator (see Monte Carlo Methods and Bayesian Computation: Overview; Markov Chain Monte Carlo Methods). The main advantage of this extension lies in the fact, discussed elsewhere, that MCMC simulators are very flexible. Its potential drawback is that its convergence properties are typically more difficult to assess than those of a conventional importance sampler.

An approach which also combines IS and MCMC is used by DiMatteo and Kadane (2001). They employ a standard MCMC technique to compute posterior moments for a given prior. Then, in order to assess robustness relative to the prior, they propose to rerun the analysis under different priors using the initial MCMC sampler as importance sampler.

An important message which emerges from this discussion is that efficient applications of IS have to be carefully tailored to the problem under consideration. This has proved to be a significant obstacle to routine applications of IS and is especially true for Bayesian applications which can produce notoriously 'ill-behaved' and, therefore, difficult to approximate posterior densities. Actually, Bayesian statisticians have largely abandoned IS in favor of MCMC. It should be noted, however, that while MCMC can be more flexible than IS, its convergence is not easily assessed in practice and may require large numbers of MC draws. In fact, both methods can occasionally produce spectacular failures if not carefully designed and controlled.

Efficient Importance Sampling

Expanding upon an earlier contribution by Danielsson and Richard (1993), Richard and Zhang (1998) have recently proposed a generic principle for constructing efficient importance samplers in cases where ϕ is a positive function. For ease of presentation, the method will be introduced here without reference to dimensionality. A straightforward rearrangement of terms in formula [7] produces the following expression:

$$\sigma^2(a) = \int h\left[d^2(x;a)\right]\phi(x)\mathrm{d}x \qquad [10]$$

where

$$d(x;a) = \ln\left[\frac{\phi(x)}{m(x|a)I}\right] \qquad [11]$$

$$h(c) = \mathrm{e}^{\sqrt{c}} + \mathrm{e}^{-\sqrt{c}} - 2 \qquad [12]$$

Note that h is monotone convex on R_+ and that $h(c) \geq c$. Minimization of $\sigma^2(a)$ with respect to a requires nonlinear optimization. Consider, therefore, the simpler function

$$q(a) = \int [\ln\phi(x) - c - \ln m(x|a)]^2\phi(x)\mathrm{d}x \qquad [13]$$

where c stands for an intercept in place of the unknown $\ln I$. Next, one selects an initial sampler, say $m(x|a_0)$ – it could be $\mu(x)$ in formula [2], or any other sampler based, for example on a local approximation of $\phi(x)$ of the sort used by Tierney and Kadane (1986). An MC approximation to $q(a)$ is then given by

$$\widehat{q}_R(a) = \frac{1}{R}\sum_{i=1}^{R}[\ln\phi(x) - c - \ln m(x|a)]^2\omega_0(x)\big|_{x=\tilde{x}_i^0} \qquad [14]$$

where

$$\omega_0(x) = \frac{\phi(x)}{m(x|a_0)} \qquad [15]$$

and $\{\tilde{x}_i^0; i: 1 \to R\}$ denotes a set of R i.i.d. draws from $m(x|a_0)$. If, furthermore, $m(x|a)$ belongs to the exponential family of distributions, then minimization of $\widehat{q}_R(a)$ with respect to a takes the form of a simple weighted linear least squares problem. It may be advisable to omit the weight function $\omega_0(x)$

if it exhibits excessive variance in cases where $m(x|a_0)$ is found to provide a poor global approximation to $\phi(x)$. The method can be iterated by using as initial sampler in any given round the optimized sampler from the previous round. Experience suggests that no more than 3 to 4 iterations are required to produce a stable solution, irrespective of the initial sampler $m(x|a_0)$. In order to assess how much efficiency is lost by minimizing $q(a)$ instead of $\sigma^2(a)$, let $\widehat{a}$ and a_* denote the minimizers of q and σ^2, respectively. Taking advantage of the convexity of h, Jensen's inequality implies that

$$\sigma^2(\widehat{a}) \geq \sigma^2(a_*) \geq h[q(a_*)] \geq h[q(\widehat{a})] \qquad [16]$$

MC estimates of the two bounds are immediate byproducts of the minimization of $\widehat{q}_R(a)$. Unless they were found to be far apart, there would be no reasons for solving the more complex minimization problem associated with $\sigma^2(a)$.

The method is extremely accurate and fast in all cases where the integrand ϕ can be well approximated by a sampler from the exponential family of distributions. The real strength of the method lies in very high-dimensional (1000^+) integration of 'well-behaved' integrands. High-dimensional minimization of $\widehat{q}_R(a)$ does require an additional factorization which is not discussed here. The final algorithm is one whereby minimization is recursively carried out one dimension at a time. It has proved useful for likelihood evaluation in dynamic latent variable models such as the one discussed earlier in Durbin and Koopman (1997). Liesenfeld and Richard (2000) successfully apply Efficient Importance Sampling (EIS) to estimate parametric as well as semi-nonparametric dynamic stochastic volatility models for three daily financial series (IBM stock prices, S&P 500 stock index, and Dollar/Deutsche Mark exchange rate). Dimensions of integration are of the order of 4700. In each case highly accurate estimates of the likelihood function are obtained with as few as $R = S = 50$ MC draws and each individual likelihood evaluation requires on the order of 8 s on a Pentium II 466 MHz notebook.

Such outstanding performance originates from the fact that these high-dimensional integrands turn out to be well-behaved, reflecting the fact that the data happen to be quite informative on the unobserved volatilities. A pilot application to a logit panel model with random effects along both dimensions had proved equally successful (see Richard and Zhang, 1998 for details).

Smooth Functional Integration

In numerous applications, such as likelihood function evaluation, the integral to be evaluated is itself a function of some argument δ, say

$$I(\delta) = \int_{D(\delta)} \phi(x;\delta)\mathrm{d}x, \quad \delta \in \Delta \qquad [17]$$

The argument δ is then carried along in all the formulae previously discussed. Most importantly, one cannot expect a single sampler to be efficient for all δ's. Hence, IS requires the selection of a particular a, say $a(\delta)$, for each relevant value of δ. If, furthermore, $I(\delta)$ has to be optimized with respect to δ, then smoothness of the functional approximation $\widehat{I}_S(\delta)$ becomes critical and cannot be secured with independent pointwise MC estimation, however accurate.

In such cases, it becomes essential that all IS sequences $\{\tilde{x}_i(a(\delta));\ \ i:1\rightarrow S\}$ be obtained by transformation of a common sequence of random draws $\{u_i;\ i:\ 1 \rightarrow S\}$ from a distribution which does not depend on a, say

$$\tilde{x}_i(a) = H(u_i;a), \quad i:1\rightarrow S, \quad \forall a \in A \qquad [18]$$

The u_i's, the so-called common random numbers, would typically be uniforms (in which case H denotes the inverse of the distribution function of x given a) or standardized normals (when x given a is itself normally distributed). See, e.g., Devroye (1986) for detailed descriptions of such transformations. Note, in particular, that inversion of a distribution function can be a computer-intensive operation but, nevertheless, is indispensable for smoothness. (The use of carefully designed interpolation techniques can significantly reduce computing times.) It should be noted that smoothness is not only required for numerical convergence of an optimization algorithm but also plays a central role in the derivation of the asymptotic properties of a broad range of simulation estimators. See, e.g., Pakes and Pollard (1989) or Gouriéroux and Monfort (1996).

Conclusion

IS is one of the key techniques currently available for the evaluation of analytically intractable integrals by MC simulation. It performs at its best when used in combination with 'acceleration' techniques such as, e.g., control variates, mixtures, common random numbers. Very high-dimensional (1000^+) integration is feasible as long as the integrand is reasonably well-behaved. Further developments are required to guide the design of efficient IS samplers. IS is not an all-purpose technique and lack of flexibility in the construction of samplers may complicate its application to ill-behaved integrands, for which alternative methods of integration such as MCMC might prove more useful. Nevertheless, IS has proved to be a remarkably useful technique for a wide range of applications including very high-dimensional integrations.

Abstract

The recent growth of Bayesian methods in statistics and the applied sciences has been heavily influenced by developments in Monte Carlo computational methods. This article features a summary of the main tools with particular emphasis on the dominant role played by Markov chain Monte Carlo methods for dealing with practically all aspects of Bayesian inference, from estimation of parameters, to prediction and model choice. Selected applications that attest to the continuing importance and viability of these methods are referenced.

Introduction

Monte Carlo simulation methods and, in particular, Markov chain Monte Carlo methods, play a large and prominent role in the practice of Bayesian statistics, where these methods are used to summarize the posterior distributions that arise in the context of the Bayesian prior–posterior analysis. Monte Carlo methods are used in practically all aspects of Bayesian inference, for example, in the context of prediction problems and in the computation of quantities, such as the marginal likelihood, that are used for comparing competing Bayesian models.

Suppose that $\pi(\psi|y,\mathscr{M}) \propto p(\psi|\mathscr{M})f(y|\psi,\mathscr{M})$ is the posterior density for a set of parameters $\psi \in \mathscr{R}^d$ in a particular Bayesian model $p(\psi|\mathscr{M})$ and sampling density or likelihood function $f(y|\psi,\mathscr{M})$ and that interest centers on the posterior mean $\eta = \int_{\mathscr{R}^d} \psi\pi(\psi|y,\mathscr{M})\mathrm{d}\psi$. As an illustration of this general setting, consider binary data $y_i \in \{0, 1\}$ modeled by the probabilities $\Pr(y_i = 1|\psi) = \Phi(x_i < \psi)$, where Φ is the standard normal cumulative distribution function, x_i are covariates and ψ is an unknown vector of parameters. The posterior distribution of ψ given n independent measurement $y = (y_1,\ldots,y_n)$ is proportional to

$$\pi(\psi|y,\mathscr{M}) \propto p(\psi|\mathscr{M}) \prod_{i=1}^{n} \Phi\left(x_i'\psi\right)^{y_i} \left(1 - \Phi\left(x_i'\psi\right)\right)^{(1-y_i)}$$

and the goal is to summarize this density.

Now suppose that a sequence of variates $\{\psi^{(1)},\ldots,\psi^{(M)}\}$ drawn from $\pi(\psi|y,\mathscr{M})$ are available and one computes the sample average of these draws. Under any set of conditions that allow use of the strong law of large numbers, it follows that the sample average is simulation consistent, converging to the posterior mean as the simulation sample M goes to infinity. This then is the essence of the Monte Carlo method: to compute an expectation, or to summarize a given density, sample the density by any method that is appropriate and use the sampled draws to estimate the expectation and to summarize the density.

The sampling of the posterior distribution is, therefore, the central focus of Bayesian computation. One important breakthrough in the use of simulation methods was the realization that the sampled draws need not be independent, that simulation consistency can be achieved with correlated draws. The fact that the sampled variates can be correlated is of immense practical and theoretical importance and is the defining characteristic of Markov chain Monte Carlo methods, popularly referred to by the acronym MCMC, where the sampled draws form a Markov chain (*see* Markov Chain Monte Carlo Methods). The idea behind these methods is simple and extremely general. In order to sample a given probability distribution, referred to as the target distribution, a suitable Markov chain is constructed with the property that its limiting, invariant distribution is the target distribution. Once the Markov chain has been constructed, a sample of draws from the target distribution is obtained by simulating the Markov chain a large number of times and recording its values. Within the Bayesian framework, where both parameters and data are treated as random variables, and inferences about the parameters are conducted conditioned on the data, the posterior distribution of the parameters provides a natural target for MCMC methods.

Markov chain sampling methods originate with the work of Metropolis et al. (1953) in statistical physics. A crucial and landmark extension of the method was made by Hastings (1970) leading to a method that is now called the Metropolis–Hastings algorithm. This algorithm was first applied to problems in spatial statistics and image analysis (Besag, 1974). A resurgence of interest in MCMC methods started with the papers of D. Geman and S. Geman (1984) who developed an algorithm, a special case of the Metropolis method that later came to be called the Gibbs sampler, to sample a discrete distribution, Tanner and Wong (1987) who proposed a MCMC scheme involving 'data augmentation' to sample posterior distributions in missing data problems, and Gelfand and Smith (1990) where the value of the Gibbs sampler was demonstrated for general Bayesian inference with continuous parameter spaces.

Markov Chain Monte Carlo Methods

The Metropolis–Hastings Algorithm

This powerful algorithm provides a general approach for producing a correlated sequence of draws from the target density $\pi(\psi)$ that may be difficult to sample by a classical independence method. As before, let $\pi(\psi)$ denote the density

that one wishes to sample, where one can assume for simplicity that the density is absolutely continuous; and let $q(\psi, \psi')$ denote a source density for a candidate draw ψ' given the current value ψ in the sampled sequence. The density $q(\psi, \psi')$ is referred to as the proposal or candidate-generating density. Then, the M–H algorithm is defined by two steps: a first step in which a proposal value is drawn from the candidate-generating density and a second step in which the proposal value is accepted or rejected according to a probability given by

$$\alpha(\psi,\psi') = \begin{cases} \min\left[\dfrac{\pi(\psi')q(\psi',\psi)}{\pi(\psi)q(\psi,\psi')}, 1\right] & \text{if } \pi(\psi)q(\psi,\psi') > 0 \\ 1 & \text{otherwise} \end{cases} \quad [1]$$

If the proposal value is rejected, then the next sampled value is taken to be the current value; which means that when a rejection occurs the current value is repeated. Given the new value, the same two-step process is repeated and the cycle iterated a large number of times. A full expository discussion of this algorithm, along with a derivation of the method from the logic of reversibility, is provided by Chib and Greenberg (1995).

The M–H method delivers variates from π under quite general conditions. A weak requirement for a law of large numbers for sample averages based on the M–H output involve positivity and continuity of $q(\psi, \psi')$ for (ψ, ψ'), and connectedness of the support of the target distribution. In addition, if π is bounded then conditions for ergodicity, required to establish the central limit theorem, are satisfied. A discussion of the conditions and the underlying Markov chain theory that justifies these methods was first provided by Tierney (1994) and summarized recently by Robert and Casella (1999). Of course, the variates are from π only in the limit as the number of iterations becomes large but, in practice, after an initial burn-in phase consisting of (say) n_0 iterations, the chain is assumed to have converged and subsequent values are taken as approximate draws from π. Theoretical calculation of the burn-in is not easy, so it is important that the proposal density be chosen to ensure that the chain makes large moves through the support of the target distribution without staying at one place for many iterations. Generally, the empirical behavior of the M–H output is monitored by the autocorrelation time of each component of ψ defined as

$$\left\{1 + 2\sum_{x=1}^{\mathscr{M}}\left(1 - \frac{s}{\mathscr{M}}\right)\rho_{ks}\right\} \quad [2]$$

where ρ_{ks} is the sample autocorrelation at lag s for the kth component of ψ, and by the acceptance rate which is the proportion of times a move is made as the sampling proceeds. Because independence sampling produces an autocorrelation time that is theoretically equal to one, and Markov chain sampling produces autocorrelation times that are bigger than one, it is desirable to tune the M–H algorithm to get values close to one, if possible.

Given the form of the acceptance probability $\alpha(\psi, \psi')$ it is clear that the M–H algorithm does not require knowledge of the normalizing constant of $\pi(\cdot)$. Furthermore, if the proposal density satisfies the symmetry condition $q(\psi, \psi') = q(\psi', \psi)$, the acceptance probability reduces to $\pi(\psi')/\pi(\psi)$; hence, if $\pi(\psi') \geq \pi(\psi)$, the chain moves to ψ', otherwise it moves to ψ' with probability given by $\pi(\psi')/\pi(\psi)$. The latter is the algorithm originally proposed by Metropolis et al. (1953).

Different proposal densities give rise to specific versions of the M–H algorithm, each with the correct invariant distribution π. One family of candidate-generating densities is given by $q(\psi, \psi') = q(\psi' - \psi)$. The candidate ψ' is thus drawn according to the process $\psi' = \psi + z$, where z follows the distribution q, and is referred to as the *random walk M–H* chain. The random walk M–H chain is perhaps the simplest version of the M–H algorithm and is quite popular in applications. One has to be careful, however, in setting the variance of z because if it is too large it is possible that the chain may remain stuck at a particular value for many iterations while if it is too small the chain will tend to make small moves and move inefficiently through the support of the target distribution.

Hastings (1970) considers a second family of candidate-generating densities that are given by the form $q(\psi, \psi') = q(y)$. Tierney (1994) refers to this as an *independence M–H chain* because the candidates are drawn independently of the current location ψ. Chib and Greenberg (1994, 1995) implement such chains by matching the proposal density to the target at the mode by a multivariate normal or multivariate-t distribution with location given by the mode of the target and the dispersion given by inverse of the Hessian evaluated at the mode.

The Multiple-block M–H Algorithm

In applications when the dimension of ψ is large it may be preferable, as discussed by Hastings (1970), to construct the Markov chain simulation by first grouping the variables ψ into smaller blocks. For simplicity suppose that two blocks are adequate and that ψ is written as (ψ_1, ψ_2), with $\psi_k \in \Omega_k \subseteq \mathscr{R}^{d_k}$. In that case the M–H algorithm requires the specification of two proposal densities,

$$q_1(\psi_1, \psi_1' | \psi_2); \quad q_2(\psi_2, \psi_2' | \psi_1)$$

one for each block ψ_k, where the proposal density q_k may depend on the current value of the remaining block. Also, define

$$\alpha(\psi_1, \psi_1' | \psi_2) = \min\left\{\frac{\pi(\psi_1', \psi_2)q_1(\psi_1', \psi_1 | \psi_2)}{\pi(\psi_1, \psi_2)q_1(\psi_1, \psi_1' | \psi_2)}, 1\right\} \quad [3]$$

and

$$\alpha(\psi_2, \psi_2' | \psi_1) = \min\left\{\frac{\pi(\psi_1, \psi_2')q_2(\psi_2', \psi_2 | \psi_1)}{\pi(\psi_1, \psi_2)q_2(\psi_2, \psi_2' | \psi_1)}, 1\right\} \quad [4]$$

as the probability of move for block ψ_k conditioned on the other block. Then, in what may be called the multiple-block M–H algorithm, one cycle of the algorithm is completed by updating each block, say sequentially in fixed order, using a M–H step with the above probability of move, given the most current value of the other block.

The extension of this method to more than two blocks is straightforward.

The Gibbs Sampling Algorithm

Another MCMC method, which is a special case of the multiple-block M–H method, is called the Gibbs sampling

method and was brought into statistical prominence by Gelfand and Smith (1990). An elementary introduction to Gibbs sampling is provided by Casella and George (1992). To describe this algorithm, suppose that the parameters are grouped into two blocks (ψ_1, ψ_2) and each block is sampled according to the *full conditional distribution* of block ψ_k, defined as the conditional distribution under π of ψ_k given the other block. In parallel with the multiple-block M–H algorithm, the most current value of the other block is used in deriving the full conditional distribution. Derivation of these full conditional distributions is usually quite simple since, by Bayes' theorem, each full conditional distribution $\pi(\psi_1|\psi_2)$ and $\pi(\psi_2|\psi_1)$ are both proportional to $\pi(\psi_1,\psi_2)$, the joint distribution of the two blocks. In addition, the powerful device of data augmentation, due to Tanner and Wong (1987), in which latent or auxiliary variables are artificially introduced into the sampling, is often used to simplify the derivation and sampling of the full conditional distributions. For further details *see* Markov Chain Monte Carlo Methods.

Implementation Issues

In implementing a MCMC method it is important to assess the performance of the sampling algorithm to determine the rate of mixing and the size of the burn-in (both having implications for the number of iterations required to get reliable answers). A large literature has now emerged on these issues, for example, Tanner (1996, Section 6.3), Cowles and Carlin (1996), Gamerman (1997, Section 5.4), and Robert and Casella (1999).

Writing at the turn of the millenium, the more popular approach is to utilize the sampled draws to assess both the performance of the algorithm and its approach to the stationary, invariant distribution. Several such relatively informal methods are now available. Perhaps the simplest and most direct are autocorrelation plots (and autocorrelation times) of the sampled output. Slowly decaying correlations indicate problems with the mixing of the chain. It is also useful in connection with M–H Markov chains to monitor the acceptance rate of the proposal values with low rates implying 'stickiness' in the sampled values and thus a slower approach to the invariant distribution.

Somewhat more formal sample-based diagnostics are also available in the literature, as summarized in the routines provided by Best et al. (1995) and now packaged in the BOA program. Although these diagnostics often go under the name 'convergence diagnostics' they are in principle approaches that detect *lack* of convergence. Detection of convergence based entirely on the sampled output, without analysis of the target distribution, is extremely difficult and perhaps impossible. Cowles and Carlin (1996) discuss and evaluate thirteen such diagnostics (for example, those proposed by Geweke (1992), Gelman and Rubin (1992), Zellner and Min (1995), amongst others) without arriving at a consensus.

While implementing MCMC methods it is important to construct samplers that mix well (mixing being measured by the autocorrelation times) because such samplers can be expected to converge more quickly to the invariant distribution. As a general rule, sets of parameters that are highly correlated should be treated as one block when applying the multiple-block M–H algorithm. Otherwise, it would be difficult to develop proposal densities that lead to large moves through the support of the target distribution and the sampled draws would tend to display autocorrelations that decay slowly. Liu (1994) and Liu et al. (1994) discuss possible strategies in the context of three-block Gibbs MCMC chains. Roberts and Sahu (1997) provide further discussion of the role of blocking in the context of Gibbs Markov chains.

Additional Uses of MCMC Methods in Bayesian Inference

MCMC methods provide an elegant solution to the problem of prediction in the Bayesian context. The goal is to summarize the Bayesian predictive density defined as

$$f(y_f|y,\mathscr{M}) = \int f(y_f|y,\mathscr{M},\theta)\pi(\theta|y,\mathscr{M})\mathrm{d}\theta, \qquad [5]$$

where $f(y_f|y,\mathscr{M},\theta)$ is the conditional density of future observations y_f given $(y,\mathscr{M},\theta)$. In general, the predictive density is not available in closed form. However, this is not a problem when a sample of draws from the posterior density is available. If one simulates

$$y_f^{(i)} \sim f\left(y_f|y,\mathscr{M},\theta^{(j)}\right) \qquad [6]$$

for each sampled draw $\theta^{(j)}$, then the collection of simulated values $\{y_f^{(1)},\ldots,y_f^{(M)}\}$ is a sample from the Bayes prediction density $f(y_f|y,\mathscr{M})$. The simulated sample can be summarized in the usual way by the computation of sample averages and quantiles.

MCMC methods have also been widely applied to the problem of the model choice. Suppose that there are K possible models $\mathscr{M}_1,\ldots,\mathscr{M}_K$ for the observed data defined by the sampling densities $\{f(y|\theta_k,\mathscr{M}_k)\}$ and proper prior densities $\{p(\theta_k|\mathscr{M}_k)\}$ and the objective is to find the evidence in the data for the different models. In the Bayesian approach this question is answered by placing prior probabilities $\Pr(\mathscr{M}_k)$ on each of the K models and using the Bayes calculus to find the posterior probabilities $\{\Pr(\mathscr{M}_1|y),\ldots,\Pr(\mathscr{M}_K|y)\}$ conditioned on the data but marginalized over the unknowns θ_k (Jeffreys, 1961 and Kass and Raftery, 1995). Specifically, the posterior probability of $\mathscr{M}_k$ is given by the expression

$$\Pr(\mathscr{M}_k|y) = \frac{\Pr(\mathscr{M}_k)m(y|\mathscr{M}_k)}{\sum_{i=1}^{K}\Pr(\mathscr{M}_l)m(y|\mathscr{M}_l)} \propto \Pr(\mathscr{M}_k)m(y|\mathscr{M}_k), (k \le K) \qquad [7]$$

where $m(y|\mathscr{M}_k)$ is the marginal likelihood of $\mathscr{M}_k$.

A central problem in estimating the marginal likelihood is that it is an integral of the sampling density over the prior distribution of θ_k. Thus, MCMC methods, which deliver sample values from the posterior density, cannot be used to directly average the sampling density. In addition, taking draws from the prior density to do the averaging produces an estimate that is simulation consistent but highly inefficient because draws from the prior density are not likely to be in high density regions of the sampling density $f(y|\theta_k,\mathscr{M}_k)$. A natural way to correct this problem is by the method of importance sampling.

If we let $h(\theta_k, \mathscr{M}_k)$ denote a suitable importance sampling function, then the marginal likelihood can be estimated as

$$\widehat{m}_1(y|\mathscr{M}_k) = M^{-1}\sum_{j=1}^{M}\frac{f\left(y\middle|\theta_k^{(j)},\mathscr{M}_k\right)p\left(\theta_k^{(j)}\middle|\mathscr{M}_k\right)}{h\left(\theta_k^{(j)}\middle|\mathscr{M}_k\right)} \quad [8]$$

$$\theta_k^{(j)} \sim h\left(\theta_k^{(j)}\middle|\mathscr{M}_k\right) \quad (j \le M)$$

This method is useful when it can be shown that the ratio is bounded, which can be difficult to check in practice, and when the sampling density is not expensive to compute; this, unfortunately, is often not so. Gelfand and Dey (1994) propose an estimator that is based on the posterior simulation output. Another method for finding the marginal likelihood is due to Chib (1995). The marginal likelihood, by virtue of being the normalizing constant of the posterior density, can be expressed as

$$m(y|\mathscr{M}_k) = \frac{f(y|\theta_k,\mathscr{M}_k)p(\theta_k|\mathscr{M}_k)}{\pi(\theta_k|y,\mathscr{M}_k)} \quad [9]$$

which is an identity in θ_k.Based on this expression an estimate of the marginal likelihood on the log-scale is given by

$$\log \widehat{m}(y|\mathscr{M}_k) = \log f\left(y\middle|\theta_k^*,\mathscr{M}_k\right) + \log p\left(\theta_k^*\middle|\mathscr{M}_k\right) - \log \widehat{\pi}\left(\theta_k^*\middle|y,\mathscr{M}_k\right) \quad [10]$$

where θ_k^* denotes an arbitrarily chosen point and $\widehat{\pi}(\theta_k^*|y,\mathscr{M}_k)$ is the estimate of the posterior density at that single point. To estimate this posterior ordinate Chib (1995) utilizes the Gibbs output in conjunction with a decomposition of the ordinate into marginal and conditional components. Chib and Jeliazkov (2001) extend that approach for output produced by the Metropolis–Hastings algorithm. A comparison of different estimators of the marginal likelihood is provided by Chen and Shao (1997).

When one is presented with a large collection of candidate models, each with parameters $\theta_k \in B_k \subseteq R^{d_k}$, direct fitting of each model to find the marginal likelihood can be computationally expensive. In such cases it may be more fruitful to utilize model space–parameter space MCMC algorithms that eschew direct fitting of each model for an alternative simulation of a 'mega model' where a model index random variable, denoted as $\mathscr{M}$, taking values on the integers from 1 to K, is sampled in tandem with the parameters. The posterior distribution of $\mathscr{M}$ is then computed as the frequency of times each model is visited. Methods for doing this have been proposed by Carlin and Chib (1995) and Green (1995) which are discussed in article 2.1.76. Both methods are closely related as shown by Dellaportas et al. (1998) and Godsill (1998). The problem of variable selection in regression has also been tackled in this context starting with George and McCulloch (1993).

An Example

Markov chain Monte Carlo methods have proved enormously popular in Bayesian statistics (see for example, Gilks et al. 1996) where these methods have opened up vistas that were unimaginable fifteen years ago.

As an illustration of how MCMC methods are designed in a Bayesian context, we return to the binary data problem discussed in the introduction and describe the approach of Albert and Chib (1993) that has found many applications. Recall that the posterior distribution of interest is proportional to

$$\pi(\beta|y,\mathscr{M}) \propto p(\beta|\mathscr{M})\prod_{i=1}^{n} p_i^{y_i}(1-p_i)^{(1-y_i)} \quad [11]$$

where $p_i = \Phi(x_i'\psi)$. To analyze this probit model, and other models for binary and ordinal data, Albert and Chib introduce latent variables and write $z_i = x_i'\psi + \varepsilon_i$ where ε_i is $\mathscr{N}(0, 1)$ and let $y_i = I[z_i > 0]$ where $I[\cdot]$ is the indicator function. This two-equation specification is equivalent to the binary probit regression model since $\Pr(y_i = 1|\psi) = \Pr(z_i > 0|\psi) = \Phi(x_i'\psi)$, as required. The Albert–Chib algorithm now consists of simulating the joint posterior distribution of (ψ, Z), where $Z = (z_1,\ldots,z_n)$. The MCMC simulation is implemented by sampling the conditional distributions $[\psi|y, Z]$ and $[Z|y, \psi]$. The first of these distributions depends only on Z (and not on y) and is obtained by standard Bayesian results on normal linear models. The second factors into a product of independent distributions $[z_i|y_i, \psi]$. The knowledge of y_i merely restricts the support of the normal distribution $z_i|\psi$; if $y_i = 0$, then $z_i \le 0$ and if $y_i = 1$, then $z_i 0$. Suppose that a priori $\psi \sim \mathscr{N}_k(\psi_0, C_0)$, where ψ_0 and C_0 are known hyperparameters. Then, a sample of ψ and Z from the posterior distribution is obtained by iterating on the following steps:

a. sample ψ from the distribution $\mathscr{N}_k(\widehat{\psi}, C)$, where $\widehat{\psi} = C\left(C_0^{-1}\psi_0 + \sum_{i=1}^{n} x_i z_i\right), C = \left(B_0^{-1} + \sum_{i=1}^{n} x_i x_i'\right)^{-1}$;
b. sample z_i from $\mathscr{T}\mathscr{N}_{(-\infty,0)}(x_i'\psi, 1)$ if $y_i = 0$ and from $\mathscr{T}\mathscr{N}_{(0,\infty)}(x_i'\psi, 1)$ if $y_i = 1$, where $\mathscr{T}\mathscr{N}_{(a,b)}(\mu, \sigma^2)$ denotes the $\mathscr{N}(\mu, \sigma^2)$ distribution truncated to the region (a, b).

At this time, considerable work on MCMC methods and applications continues to emerge, a testament to the importance and viability of MCMC methods in Bayesian analysis.

Abstract

Barrington Moore analyzed the consequences of political systems for human happiness and misery, the nature of exploitation, reciprocity in relations between the people and political elites, and the role of moral codes in producing justice and identifying injustice. His most famous book, *Social Origins of Dictatorship and Democracy*, explored the contribution to shaping sociopolitical change made by declining sociopolitical interests; in particular, powerful classes such as the landed aristocracy and the peasantry who face losing out or even destruction as cities become more influential, industry and the urban working class grow in importance, and central government acquires greater control.

Brief Biography

Family

Barrington Moore Jr. (1913–2005) is best known as the author of the classic *Social Origins of Dictatorship and Democracy* (henceforth *Social Origins*, Moore, 1966), which won the Woodrow Wilson Foundation Award in 1968, and the MacIver Award in 1969. Moore was the son of Barrington Moore Sr., a distinguished ecologist who made his career as a forestry engineer. His mother, Muriel Hennen Morris, a New York socialite, was the daughter of a successful trader with interests in China and Republican politics. After their marriage, his parents moved to the rugged environment of New Mexico where his father's forestry work was based. The marital relationship was a troubled one and when the couple finally split up, the young Barrington, aged 9 years, was taken into the household of his step-grandfather, Lewis Cass Ledyard. He was a successful corporate lawyer who became J. P. Morgan's private attorney and acquired substantial business interests. The Ledyard's social circle reached to the top of high society on the East Coast, including the Vanderbilts, Rockefellers, and Roosevelts. Barrington Moore Jr.'s grandparents brought him up in Newport, Rhode Island, on their Sunset Ridge estate, where a multigabled mansion flanked by trees looked out upon a many-acred lawn.

Education and Intellectual Influences

Moore's earliest educational experiences were not pleasant. He did not enjoy his 6 years at St George's private boarding school in Newport, where he suffered bullying, but at the age of 20 years, he was able to escape to Williams College in Massachusetts. There he majored in Latin and took eight courses in Attic Greek, giving him a thorough grounding in classical and medieval history. When he graduated, he was elected to Phi Beta Kappa, the elite American society for outstanding students in the liberal arts and science, founded in 1776.

At Williams, Moore also took a political science course that introduced him to the work of William Graham Sumner and Albert Galloway Keller. Moore credited these two very different scholars for his own abiding interest in problems relating to inequality, authority, ideological obscurantism, totalitarian regimes, and the causes of human misery. Later, at Yale, Moore carried out graduate work in the social sciences influenced both by Kellner, his supervisor, and G.P. Murdoch, director of the Cross-Cultural Survey (see Jackall, 2001; Snyder, 2007).

Moore completed a doctoral thesis on social stratification that applied a cross-national comparative approach in a strongly positivist spirit. Subsequently, he realized the inadequacy of this approach. Sumner and Kellner were partially displaced as background influences by Gaetano Mosca. More generally, in later years, Moore moved beyond positivism and combined his comparative-historical approach with two theoretical tendencies. One was a modified utilitarianism that assumed human beings generally abhor the misery brought by war, hunger, cruelty, and intolerance (for example, in *Reflections on the Causes of Human Misery and on Certain Proposals to Eliminate Them*; henceforth *Reflections*, Moore, 1972). The other was a quasi-Hegelian search for signs of emancipatory forces that might realize the human potentiality for creating rational and decent societies. He looked for glimmers of this in the rising tide of democracy in the United States post-1776, France post-1789, and England post-1832 (in *Social Origins*) and in the revolutionary upsurge in Germany after the World War I (in *Injustice. The Social Bases of Obedience and Revolt*; henceforth *Injustice*, Moore, 1978).

Career

As an adult, Moore enjoyed a substantial private income. This background provided a solid material and cultural base for his strong independence of mind and character. It allowed him to teach and research without becoming overly troubled with the task of climbing the professional ladder in order to acquire honors. Nor did he seek to build up influence by creating a 'school' or a network of former students in strategic academic posts. However, he earned considerable respect among fellow scholars. A number of his former students such as Theda Skocpol and Charles Tilly have paid tribute to his strong influence. Moore's colleagues in the American Sociological Association created the annual Barrington Moore Book for the best book in comparative and historical sociology.

At the start of his career, Moore was given a strong push toward an approach to social science that was more methodologically sophisticated, morally sensitive, and politically aware by his work for the American government during World

War II. He served as a policy analyst, working in the Department of Justice and the Office of Strategic Studies (OSS). At OSS, Moore was assigned to a team led by Herbert Marcuse, who became his long-term friend and intellectual sparring partner. The OSS, precursor of the Central Intelligence Agency, was in effect the largest social science research organization in the United States during the war years. Both Moore and his wife Elizabeth C Moore are to be found on the OSS list of employees in the mid-1940s. They met when they worked in the same office at the Department of Justice, and married in 1944. Elizabeth (or Betty), who died in 1992, was his main intellectual and life companion.

After the war, Moore taught at the University of Chicago before moving to Harvard in 1948. He did not stay long in the Social Relations Department, where the Parsonian paradigm, to which he was unsympathetic, prevailed, but instead he made his base at the Russian Research Center. He joined this institution in 1951 and remained there for the rest of his working life, researching and also teaching small classes of undergraduates and graduates. Moore greatly valued the resource provided by Harvard's Widener Library, not least as a source of empirical data, including statistical materials. For all his concerns with moral and theoretical issues, Moore was punctilious and precise in his treatment of factual materials, especially in a comparative context. His typical work pattern over many years was to spend much of the winter gathering together research materials in Harvard, often working in his office at home, and then spend a great deal of the summer on his yacht, along with his wife Betty, working on various writing projects.

Major Publications

Before *Social Origins of Dictatorship and Democracy*

Certain themes dominate Moore's major publications. These include the consequences of political systems for human happiness and misery, the nature of exploitation, reciprocity in relations between the people and political elites, and the role of moral codes in producing justice and identifying injustice. All were present in his first important book, entitled *Soviet Politics – the dilemma of power* (Moore, 1950). This book focuses on two major issues. One is the impact on Soviet government and political organization made by the complex and unequal division of industrial labor. The other is the conflict between the egalitarian goals of the Bolsheviks, as proclaimed in their ideology, and the inequalities generated by the political means the Bolsheviks adopted to achieve and keep power in a rapidly industrializing society while facing threats from external and internal enemies.

Moore traces the tactics employed by Lenin and his successor, Stalin, and emphasizes that Bolshevik ideology limited the flexibility of the regime during the period of the New Economic Policy in the 1920s when markets and private enterprise were officially permitted to a limited degree. In a companion study, *Terror and Progress USSR* (Moore, 1954), Moore explores how the regime might be likely to change in the wake of Stalin's death. He pays particular attention to the threat to totalitarian bureaucracy and the official ideology that was posed by two things: the increased salience of social stratification, bringing to prominence a new emphasis on tradition, and the increasingly prominent role being played by apolitical technical experts with their belief in scientific rationality.

In both his Soviet studies, Moore is using his analysis of this specific national case to consider conflicts and affinities more generally present in relations between the following: the political purposes of rulers, the functional requirements of social life, the potentialities and restrictions built into specific cultural symbols, and the way human beings typically perceive their worlds and act within them.

The issues just mentioned contributed to two related inquiries that continue throughout Moore's career. The first is what empirical generalizations may be made about the processes whereby peasants and other kinds of workers become citizens within modern bureaucratic states. The second is what kind of social existence can a citizen legitimately expect to enjoy and how do they typically respond when decent conditions are denied to them (see Smith 1983)?

In *Political Power and Social Theory* (Moore, 1958), Moore sets down his thoughts on modes of acquiring political power, totalitarianism in preindustrial societies, the family, conformity in industrial societies, and methodologies of social science. The essays are designed to attack commonly held but unsustainable assumptions. For example, Moore argues that some institutions, such as totalitarianism, thought to be modern, are also found in premodern times; that some 'essential' institutions, such as the family, thought to be universal to industrial societies, may in fact be dispensable; and that we can identify certain recurrent cycles of institutional change, which involve changes in levels of centralization, integration, and legitimacy within sociopolitical orders.

The first essay, 'Notes on the process of acquiring power,' is a *tour de force*, demonstrating theoretical links and empirical similarities between the rise of the Bolsheviks, the papacy, the Bourbon monarchy in France, and the early Mogul emperors. Moore assesses power-seeking strategies promoting nativism, hierarchy, and egalitarianism, as well as control-seeking strategies such as feudalism, totalitarianism, and rational bureaucracy, each of which may be found in many different societies and epochs.

The essays in *Political Power and Social Theory* were a ground-clearing exercise in which Moore sharpened his analytical tools for the following project: to develop a strategy that would enable him to apply rational analysis to discoverable facts about the empirical sociopolitical world and derive a basis for value judgments about how men and women should behave toward one another, especially as citizens and rulers. On the basis of these early essays, Moore concluded that, regretfully, moral choices had to be made in conditions of high uncertainty. However, he was working to improve that situation and the first substantial fruit of that effort was *Social Origins*, which was published in 1966.

Social Origins of Dictatorship and Democracy

The argument in *Social Origins*, which took Moore about 10 years to write, was groundbreaking in three respects. It demonstrates the large contribution to shaping sociopolitical change made by threatened sociopolitical interests; in particular by powerful or potentially powerful classes such as the landed aristocracy and the peasantry fear losing out as cities

become more influential, industry and the urban working class grow in importance, and central government acquires greater control. Another contribution is Moore's recognition that in cases of attempted rebellion, material motivations for rebellion are mingled with considerations of morality and justice, especially the subordinates' judgment about whether or not the ruling class is doing its best to govern fairly and in the interests of all. Not least, Moore insists that democracies, just as much as dictatorships, were liable to be preceded by violent events such as revolutions and civil wars, and installed under conditions of repression, temporarily at least.

Social Origins presents a comparative analysis of the moral and material conditions of groups within the configurations that bind together peasants, landlords, merchants, rulers, and public officials. On the basis of a masterly exposition, deployed over several chapters, Moore sets out to build two complementary intellectual structures. The first is a series of causal explanations of a number of rapid and dramatic structural transformations, entailing considerable violence and suffering, including the French and Chinese Revolutions. The second is a series of analyses of the morally relevant consequences of the processes whereby modernizing urban society has impinged upon the rural order.

The analytical strategies are very different in the two cases. In constructing his causal explanations, Moore typically presents his empirical findings with respect to the following: (1) the potentialities for and limits upon structural variations in the society concerned at its specific stage of development; (2) the tendencies toward cohesion and disintegration, which are actually present in that society, with particular reference to the division of labor and forms of domination; (3) the ways that specific groups perceive their material and moral interests within the society; (4) the occurrence of specific events or tendencies, which present threats to those perceived interests that are sufficiently sudden or drastic to stimulate people into action; (5) the identity of the potential allies, opponents, and victims of specific groups whose perceived interests are threatened; (6) the options in historical development that have been closed off in that society as a result of preceding sequences of historical change; (7) how threatened groups actually behave when the threat materializes; and (8) the structural outcomes to which their behavior contributes.

Applying this approach, he identifies three main routes from the preindustrial to the modern world. One leads toward democracy, an outcome that is made much likely when a strong and independent capitalist bourgeoisie emerges, ready to attack inherited obstacles to such a development. England, France, and the United States are examples, although they arrive at this point through diverse trajectories. Two other routes lead to dictatorship.

The second route is capitalist but the principal agent is a dominant landed aristocracy, which does the military and political work of clearing the space for a commercially vigorous bourgeoisie while making sure that the bourgeoisie's aspirations for democracy are kept in check. Japan and Germany are two key examples. When the peasants and urban workers demand to become part of the modernizing polity, they are incorporated through fascist techniques that give them a subordinate, obedient role.

The third route involves peasant uprisings, which weaken the rural ruling class in societies where the commercial bourgeoisie is not dynamic enough to bring about industrial modernization. This modernizing task is undertaken instead by a powerful state bureaucracy, which incorporates workers and peasants in the name of communist ideology. Russia and China are the main examples.

Moore's comparative analyses of varying patterns of conflict and solidarity within peasant communities, in France, China, Japan, and so forth, are a valuable part of *Social Origins*. So is his lengthy chapter on India, a case that does not fit easily into his typology of routes.

In assessing the morally relevant political consequences (as distinct from the causes) of modernizing processes, Moore's basic approach is to conduct a cost–benefit analysis, which weighs the costs in terms of human misery against any benefits in terms of human freedom. This calculus includes costs and benefits that might plausibly have been expected if genuinely feasible alternative patterns of development that did not occur had in fact been followed. So an element of counterfactual reasoning about opportunity costs is included (see Smith, 1984).

After *Social Origins of Dictatorship and Democracy*

In his next two books, Moore conducts a frontal attack on the problem of how criteria for value judgments may be derived from objective knowledge about human societies. In *Reflections* (Moore, 1972), he concludes that the most likely outcome of existing sociopolitical trends is the erosion of accepted codes of behavior and the collapse of political authority. However, he finds some rays of hope. For example, he reckons that it will be possible to persuade supporters of capitalism that the misery it produces is not an inevitable or necessary aspect of that system; a more humane form of capitalism is technically feasible as well as being desirable. He sets out some standards for such a society. For example, its inhabitants should expect to enjoy the following: emotional security; a broad and coherent liberal education that gives them technical and intellectual competence; and a significant degree of socioeconomic equality, sufficient to prevent a powerful establishment from controlling thought.

Moore accepts that insecurity and uncertainty in social and political life are impossible to eliminate, as are fraud and selfishness. However, they may be minimized if citizens demand that those in power exercise what he calls 'rational political authority.' Applying a quasi-utilitarian moral calculus, Moore deduces that rulers should try to govern in such a way that they minimize suffering within their societies insofar as this is humanly possible, given existing material resources, technological facilities, and organizational capacities within the society.

In *Injustice* (Moore, 1978), he looks for evidence that in practice subjects or citizens normally apply the standard just mentioned when assessing the activities of their rulers or governments. His main point is that when rulers and governments either fail to prevent or deliberately bring about suffering and misery that could have been avoided, the typical response of those who are damaged by this is intense moral outrage. In effect, *Injustice* is an amalgam of two intellectual exercises.

One is an essay on philosophical anthropology, which seeks empirical evidence for the existence of a widespread ideology of rational political authority, drawing upon data relating to societies as varied as Inuits in North Alaska, the Bantu-speaking Lovedu people of South Africa, the Kapauku Papuans, the inhabitants of Barotseland in Zambia, the Trobrian Islanders, the Semai of Malaysia, the inhabitants of ancient Greece, the Ming Empire in China, and eighteenth-century England. There is some confirmatory evidence but it falls far short of proving the case.

The other exercise, more successful, is Moore's study of the German working class, which explores the way industrial employees diagnosed their own experiences at work and proposed remedies for their disadvantageous situation. In particular, he considers the uprising in the Ruhr in 1920, and the choices open to Friedrich Ebert, German chancellor and leader of the SPD (Sozialdemokratische Partei Deutschlands) when faced with this revolt. In carrying out this analysis, Moore succeeds in drawing together two things: the shaping of working-class consciousness in a specific historical situation and the economic, political, and other macrostructural forces that determined both the constraints and opportunities facing the rebellious mining communities of the Ruhr.

After *Injustice*, Moore published four volumes of essays, each focused upon a specific theme. These were *Privacy. Studies in Social and Cultural History* (henceforth *Privacy*, Moore, 1984), *Authority and Inequality under Capitalism and Socialism. United States of America, USSR and China* (henceforth *Authority and Inequality*, Moore, 1987), *Moral Aspects of Economic Growth and Other Essays* (henceforth *Moral Aspects*, Moore, 1998), and *Moral Purity and Persecution in History* (henceforth *Moral Purity*, Moore, 2000).

Authority and Inequality was based upon the Tanner lectures that Moore delivered at Brasenose College, Oxford in 1984–85. In these lectures, Moore examines the ways that bureaucracies and markets structured relations of authority and inequality in the United States, USSR, and China, and the potential for maximizing freedom and rationality in these societies, especially by the use of rational political authority to reduce misery. He argues that industrialization has increased the viability of forms of sociopolitical organization that are both prosperous and free. This is one of the reasons why resistance to bureaucracies that fail to pursue prosperity and freedom for all is endemic, as subordinates' look after their own interests as far as possible by setting up various kinds of informal and unofficial groups in their workplaces and local neighborhoods. Rulers may try either to subvert these groups (as in Russia) or infiltrate and manipulate them (as in the United States). In China, such groupings have been especially effective in cutting officialdom down to size, as occurred during the Cultural Revolution.

Distinctive structural tensions or contradictions are found in all three countries. In Russia, the imposition of terror weakened economic initiative in the population at large and this situation has not improved following the shift from terror to technocracy that had occurred by the mid-1980s. By contrast, in China, there has been a greater commitment by government to rational political authority. Citizens and workers have been encouraged and emboldened to attack corruption. This effort has tended to divert energies from the pursuit of economic growth. Furthermore, attempts to introduce market incentives for individual enterprise have been restricted: by the vested interests of bureaucrats and workers dedicated to maintaining a guaranteed living standard ('the iron rice bowl'); by worker resistance to interference; and by the government's anxiety about the danger of creating an underemployed intelligentsia, trained and motivated for market opportunities that do not yet exist.

In the United States, there is an abiding structural contradiction between, on the one hand, the deep antiauthoritarianism and individualism of American culture and, on the other hand, the increase in bureaucratization since the 1870s. Moreover, inflation during the 1960s and 1970s undermined the ability of the market to establish a close and clear relationship between individual effort and individual reward. The struggle for advantage between groups in an inflationary context undermined the social peace established since the 1930s by the New Deal coalition of Democratic politicians, trade unions, white southerners, and various racial, ethnic, and religious minorities.

Moore concludes that the legitimacy of both the socialist and the liberal capitalist models of politics and society have suffered decay. Neither has eliminated inequality and they have brought with them the evils of, in one case, imperialism and unemployment and, in the other case, scarcity and repression. Organizational complexity and the need for coordination mean that all industrial societies are bound to limit freedom and equality in some respects. However, justice demands that appropriate rewards should go to those with socially useful competences in short supply. In fact, this does not occur. Another complication is that people intensely dislike the anxiety that accompanies industrial modernization and, as a result, they are all too ready to be seduced by fascism, nihilism, or hedonism as ways of escaping responsibility and uncertainty.

In his three other main works, Moore returns to the strategy of comparative anthropology and history undertaken in *Injustice*, pursuing themes such as privacy, moral aspects of capitalism and socialism, and moral purity in different cultural and religious traditions through history. In *Privacy* (Moore, 1984), Moore finds that in ancient Greece, private life was considered inferior to public participation in civic affairs. In Hebrew society, as recorded in the Old Testament, God's law reached deep inside the household and personal sphere. By contrast, in imperial China, rules of etiquette provided limits to the extent of intrusion imposed upon educated people. One of the great civilizing achievements of the modern West has been to challenge the priority of the public sphere and defend the private sphere against intrusion. However, Moore considers that a pathological version of privacy has developed in contemporary America, which inhibits citizens from getting involved in matters that do not directly and immediately concern them.

Many of the essays in *Moral Aspects* (Moore, 1998) overlap with Moore's other writings but two should receive individual mention. One is the title essay, 'Moral Aspects of Economic Growth: Historical Notes on Business Morality in England' (Moore, 1998, 1–53), which is part of a comparative historical project that remained uncompleted. It is largely based on a study of the laws and customs controlling trade in medieval and early modern England. During this period, business norms placed a large premium on the appearance of respectability and

social concern, including care for employees. These norms were put to the test as commercial and industrial growth eventually brought about a society in which acquiring wealth was no longer a zero-sum game in which one had to steal from others, oppress them, or simply go without. The ironic result of economic growth was that, despite the increased potential for strengthening public institutions providing social welfare, by the early nineteenth century the market was being widely described as a key arena in which individual initiative, self-reliance, and hard work provided the only road to material success. However, Moore finds that in practice, the paternalistic tinge of medieval social policy persisted. Moral concerns remained densely interwoven with economic practice.

In 'Rational Discussion: Comparative Historical Notes on Its Origins, Enemies, and Prospects' (Moore, 1998, 144–157), Moore contrasts the oratorical political culture of ancient Greece with the memorandum-based styles of the Chinese imperial bureaucracy, each designed to facilitate rational discussion, with both cultures encouraging its elites to acquire the relevant arts of speaking and writing. Turning to religion, Moore notes its tendency to raise the temperature of debate and argues that a balance is needed between enthusiasm and detachment when discussing public policy. In conclusion, Moore suggests that rational discussion is unlikely when the following conditions prevail: a high level of political excitement, an authoritarian regime repressing opposition, a powerful educated elite dominating decision making, or widespread quasi-religious certainty about how society ought to be organized.

Moore's last book, *Moral Purity* (Moore, 2000), traces ideas of purity and impurity through the Old Testament, in the religious conflicts of sixteenth-century France, during the French Revolution, and in Hinduism, Buddhism, and Confucian China. This survey leads him to the conclusion that the theory and practice of moral purity, combined with attacks upon manifestations of impurity in others, arose from monotheism, as developed in Judaism, Christianity, and Islam. These concerns were secularized during the French Revolution, which popularized the idea of revolutionary purity. The three Asian religious approaches studied were relatively free of obsessions about purity until the expansion of Western ideas and ideals transformed them, leading to Maoism, militant Hinduism, and more militant forms of Buddhism. Demands for moral purity have become global, an undesirable outcome in Moore's view.

Critical Reception and Lasting Impact of Moore's Work

The Influence of Moore's Methodology

Moore's principal concern throughout his career was to encourage social scientists to remain clear-sighted, rational, and dispassionate in considering the evidence that their research produced, wherever it led. Above all, researchers should be wary of ideological formulas and dogmatic assertions of all kinds. Moore's last book, *Moral Purity* (Moore, 2000), illustrates the danger of dogma since it argues that monotheism carries the potential for justifying self-righteous violence against hated unbelievers.

Moore's typical approach was to locate specific empirical cases in a comparative context as far as possible, while examining, in each case studied, the interplay between the human pursuit of material and moral interests and the driving force of large-scale historical processes that open up some options for action while closing others.

Moore insists that in assessing the costs and benefits of any historical outcome, whether it is a new regime that sets a new political direction, a technological innovation that transforms the industrial division of labor, or a religious revival that transforms a community's way of life, a key counterfactual question is what would have been the costs and benefits if matters had gone differently: a different regime, another kind of technology, an alternative form of religion, or no change at all?

The scale and scope of the vision embodied in Moore's methodology, combining knowledgeable detachment with alert involvement, locate him in a tradition that reaches back to Montesquieu and Alexis de Tocqueville and includes more recent practitioners such as Norbert Elias, C Wright Mills, and Albert Hirschman. Apart from a sharp negative appraisal of Talcott Parsons' 'new scholasticism' (Moore, 1953), Moore does not engage to any great extent with contemporary social and political theory. For this reason, perhaps, reviewers have sometimes found works such as *Privacy* (Moore, 1984) rather mystifying, being unfamiliar with, or unsympathetic to, Moore's long-term agenda of seeking universally shared moral criteria while remaining alert to the possible presence of long-term processes of development in cultures across space and time.

Moore's methodological approach is not reducible to short formulae and has been most effectively transmitted to students who have worked closely with him and those who have read his books with care, not least by those determined, if possible, to undermine or disprove his specific empirical generalizations or theoretical propositions. For his part, Moore welcomed such critical attention and was happy to see his own provisional conclusions improved or superseded by careful scholars.

One example of Moore's willingness to debate his conclusions is his friendly dialogue with Herbert Marcuse, who shared his interest in Soviet Marxism, the relationship between human desires and cultural constraints, the causes of human misery, and the sociopolitical dynamics of tolerance (Marcuse, 1958, 1964, 1969). They both contributed essays to a book on tolerance (Wolff et al., 1965).

Responses to *Social Origins of Dictatorship and Democracy*

Barrington Moore is best known for his resounding classic, *Social Origins* (Moore, 1966), although its renown dwindled during the mid-1990s, along with historical sociology more generally, in the face of the onslaught of ahistorical, market-oriented, rational-choice forms of theory and scholarship heavily influenced by the political success of neoliberal economics. *Social Origins* has received more critical attention since the late 1990s (e.g., Skocpol, 1998).

Moore's confrontation in *Social Origins* with both Marxian and liberal interpretations of the emergence of capitalist democracy, fascism, and communism made this book an object of intense debate across disciplines and continents

during the late 1960s and 1970s, and since then a continuing challenge to practitioners of comparative historical analysis. By 1975, *Social Origins* had been reprinted nine times in the United States.

Early reviewers had difficulty in categorizing the book, which was variously described as Marxist, Weberian, and Parsonian. While its great strengths were acknowledged, a number of justified criticisms were made: for example, there was too little consideration of relations between states and societies, processes of political decision making within the state apparatus were neglected, and the role of ideas tended to be treated as a secondary factor. Moore's predominant emphasis in *Social Origins* was upon the ramifications of processes such as the commercialization of agriculture and the progressive infiltration of governmental bureaucratic power throughout modernizing national societies.

Despite its emphasis upon the dynamics of political economy, Moore's direct approach to power relations and exploitation could not be dismissed as mere left-wing rhetoric since it came in the form of a carefully argued, dispassionate, and empirically rich thesis advanced by a man of impeccable social background rooted in the heart of the American establishment. As a result, *Social Origins* cleared the way for the positive reception in the United States during the 1970s of works such as those by Eric R Woolf and Roland Mousnier on peasant uprising (Woolf, 1971; Mousnier, 1971), Antony Giddens on the class structure of advanced societies (Giddens, 1973), Perry Anderson on historical forms of political economy (Anderson, 1974a,b), Immanuel Wallerstein's analyses of the capitalist world system (e.g., Wallerstein, 1974), Jeffrey Paige on agrarian revolutions (Paige, 1975), James Scott on peasant moral economy (Scott, 1976), and Theda Skocpol's comparative analysis of social revolutions (Skocpol, 1979).

During the 1980s and early 1990s, a strong current of serious research continued, inspired by Moore's example and subjecting his arguments to sympathetic challenge. Three examples are Jack Goldstone's discussion of revolution and rebellion in the early modern world (Goldstone, 1991), Gregory Luebbert's study of political order in interwar Europe (Luebbert, 1991), and Brian M Downing's analysis of the ways in which military modernization in early modern Europe contributed to the emergence of democracy and dictatorship (Downing, 1992).

By the time Barrington Moore's centenary arrived in 2013, the prospects of his work's survival as an intellectual force for the foreseeable future seemed good. For example, Daron Acemoglu and James A Robinson paid indirect tribute to that influence in the title of their study of the 'economic origins of dictatorship and democracy' (Acemoglu and Robinson, 2006). This book shares Moore's concern with struggles between socioeconomic interests to get their hands on their society's resources and influence the political and constitutional rules through which resource distribution is governed. However, in sharp contrast to Moore, who works through a mountain of empirical materials to arrive at his provisional generalizations, Acemoglu and Robinson begin with an a priori rational choice model from which they derive a typology of possible outcomes. These outcomes are then illustrated through empirical examples – Britain, Argentina, Singapore, and South Africa – that appear to exemplify the range of typological possibilities.

In fact, it is not reasonable to expect that Moore's comparative-historical and counterfactual methodology might be contained within a rational choice approach. This is especially the case when attention is paid to the emotional and social–psychological dynamics of political culture, a factor bracketed out by rational choice theory but an important consideration within *Reflections* (Moore, 1972) and *Social Origins* and, indeed, a central concern of Moore's book *Injustice* (Moore, 1978). In the early twenty-first century, these emotional and social–psychological dynamics are receiving considerable attention both in political science and historical sociology (e.g., Demertzis, 2013; Smith, 2006, 2013). This is yet another reason why Moore's concerns, his methods, and his example will continue to enliven debate and dialogue in the social sciences.

Moral Development and Education

Abstract

This article summarizes developmental approaches to moral education beginning with the work of Piaget and Kohlberg. Current research on moral development is reviewed including attention to the ethics of care, and social cognitive domain theory with reference to issues of culture and findings from neuroscience. Educational practices reviewed include dilemma discussion, transactive discussion, the 'Just Community School,' Developmental Discipline, domain consistent teacher discourse, and community service activities aimed at the development of the 'moral self.'

Applications of developmental psychology to moral education originated with Jean Piaget's (1932) studies of the moral development of young children. Piaget (1932) approached children's socialization through a careful study of how children interpret the rules that structure their games, and how they reason about actions that carry moral consequences. This work led him to conclude that children's natural efforts to understand the social world result in concepts of morality that shift from an earlier 'heteronomous' orientation toward adult authority and social norms to an 'autonomous' moral orientation based on children's own interpretations of fairness, reciprocity and mutual respect. In the heteronomous phase, according to Piaget (1932), children maintain a unilateral respect for adult authority and view social rules as fixed. Children's moral behavior is guided by concerns for objective consequences of their actions and a fear of external consequences. As children develop they become capable of taking into account the perspectives of others, and shift their moral orientation toward reciprocity and mutual respect. Moral obligation in the autonomous phase stems from this understanding of the requirements of fairness rather than being based upon external rules and sanctions.

Although Piaget did not engage in educational research, his conclusions about children's heteronomous and autonomous moral orientations led him to argue that early moral development is stimulated by peer interactions in which social power is more or less equalized, and is hampered by adult interventions that invoke the imposition of social norms and unilateral solutions to social conflicts that reinforce young children's heteronomous morality. Piaget concluded from this work that schools should emphasize cooperative decision-making and problem solving, nurturing moral development by requiring students to work out common rules based on fairness (DeVries and Zan, 1994). In effect, Piaget's (1932) view of moral education was the inverse of the traditional approach to character education that emphasizes the adult role in children's socialization.

Kohlberg and the Application of Moral-Stage Theory

In the 1960s Piaget's (1932) account of moral development was extended and reworked by Lawrence Kohlberg (1984). Consistent with Piaget, he proposed that children form their understandings of moral concepts such as justice, rights, and human welfare from their direct social experiences rather than acquiring them as social values from adults. Kohlberg followed the development of moral judgment beyond the ages studied by Piaget, and determined that the process of attaining moral maturity took longer and was more gradual than Piaget had proposed. Kohlberg described moral development as moving through three levels incorporating a total of six developmental stages. However, the overall pattern described by Kohlberg (1984) was in line with Piaget's basic premise that moral development involves a gradual transition from the conflation of morality with the conventions and standards of society and social authority to a principled level of moral maturity in which moral judgments are structured by underlying conceptions of fairness and human welfare.

Moral Dilemma Discussion

Kohlberg's (1984) research on moral development was part of the 'cognitive revolution' that reshaped American psychology in the 1970s. For Kohlberg, the limitations of behaviorist and social learning accounts of socialization mapped directly onto Piaget's (1932) criticisms of Durheim's (1925) vision of moral education, and traditional approaches to character education. Kohlberg (Kohlberg and Turiel, 1971) mocked the appropriation of Aristotelian philosophy by traditional character education as reducing moral education to the teaching of an arbitrary 'bag of virtues' defined by the unexamined social values of character education proponents. Moreover, he viewed the socialization approach advocated by traditional character education as contributing to the consolidation of conventional moral reasoning rather than contributing toward moral development.

Instead of teaching moral values directly, Kohlberg proposed that the core of moral education should be a focus upon moving students through the progression of stages of moral reasoning toward principled morality. Following Piaget, Kohlberg held that the process of stage change occurs gradually as a result of the efforts of individuals to resolve the contradictions or conflicts that result from the application of their moral understandings to actual moral situations. Kohlberg applied this general principle to his work on education through the use of *moral dilemma discussion*. Early research on the social experiences that contribute to stage change indicated that development is enhanced when individuals are drawn into a discussion about a moral conflict and asked to provide both a solution and justification for their position, and when

counterarguments are one stage above the moral reasoning level of the targeted students (Blatt and Kohlberg, 1975). Later, more refined studies indicated that the key to successful moral discussion was less a matter of achieving an 'optimal mismatch' in the moral reasoning stage of discussion participants, than the degree to which members of a discussion actively engaged in efforts to reconcile or integrate competing moral arguments with the goal of arriving at a shared moral position (Berkowitz and Gibbs, 1983). The 'transactive' discussion patterns that Berkowitz and Gibbs (1983) identified in their research were structurally similar to what Jurgen Habermas (1991) has defined as the 'communicative discourse' requisite for the social construction of a rationally defensible morality. The actual classroom applications of Kohlberg's moral stage theory to moral dilemma discussion did not fare as well. This approach to moral education did not translate into changes in student conduct, nor was it easily integrated within the natural flow of academic activities valued by classroom teachers (Power et al., 1989). As will be discussed below, however, recent work has effectively revived the use of classroom discussion as a tool for moral education (Nucci, 2009).

The Just Community School

Following the disappointing outcomes of the early effort at moral education through dilemma discussion, Kolhberg and his colleagues (Power et al., 1989) shifted their efforts toward a more comprehensive reform of the organization and culture of the school as a whole. What they refer to as the *just community* approach divides up students within a school into *clusters* of 40–100 students and their teachers who engage in weekly whole-group discussions focused upon arriving at just resolutions of issues and disputes that arise within the actual interactions of the students. Published reports indicate that this approach is quite effective in reducing student misconduct, and that it contributes to students' moral development (Power and Higgins-D'Alessandro, 2008). Despite its apparent effectiveness, the just community approach has not been widely adopted by school systems either in the United States or Europe where much of the research effort has been focused. Among the stated impediments to large-scale adoption of this approach is that it (1) requires radical school reform; (2) involves a substantial commitment to teacher preparation; (3) involves an initial investment of resources; and (4) is emotionally draining on participating teachers (Power and Higgins-D'Alessandro, 2008). Moreover, the Kohlberg account of moral development upon which the approach is based has been challenged by developmental psychology (Snarey and Samuelson, 2008). The latter critique, however, is not aimed at the broader educational methods employed in the just community approach. Despite these criticisms and challenges the just community approach has staunch defenders and advocates (Power and Higgins-D'Alessandro, 2008).

Moral Education and the Morality of Care

One of the most important early challenges to Kohlberg's vision of moral development and moral education focused upon the perceived overemphasis on reasoning and discourse, and the deemphasis of moral emotion (Noddings, 2002). The impetus of this critique came from claims by Carol Gilligan (1982) that Kohlberg's moral theory had overlooked a separate moral ethic of care that was said to be more characteristic of women and girls than of men and boys. The initial claims of gender differences in the 'care orientation' toward morality were largely refuted by subsequent research (Walker, 2006). However, the notion of an ethic of care was taken up by Nel Noddings (2002) and made the centerpiece of her approach to moral education. The goal of moral education according to Noddings (2002) is to develop a caring orientation marked by compassionate engagement and acts of kindness toward others along with the capacity to accept care directed toward oneself.

Noddings' (2002) concerns address an imbalance in the emphasis on reasoning that Kohlberg himself understood to be only one component of a comprehensive treatment of moral education (Kohlberg and Turiel, 1971). There has been a great deal of attention paid in recent years to the topic of moral emotion. This attention has been accompanied by suggestions for ways in which school practices might foster the emotional component of moral functioning. Unfortunately, much of what has been written has served to further the misconception that cognition and affect operate independently of one another. For example, latter-day emotivists have made claims that peoples' responses to moral events are directed by a set of inborn affective triggers, and that moral reasoning occurs after-the-fact as a means to explain our own reactions to ourselves (Greene and Haidt, 2002; Izard, 1986; Haidt, 2001). Such models are built from research indicating that humans possess a number of inborn capacities to display and to recognize in others basic emotions such as anger, sadness, and joy (Eckman, 1993), and that human infants appear to be primed to respond empathically to the distress of others (Emde et al., 2001; Ludemann, 1991). From an evolutionary/adaptive view of intelligence one may argue that such basic emotional schemata provide a 'quick and dirty' response to social problems that may be a part of our evolutionary heritage. Unmediated raw emotion, however, is hardly adaptive in the social world. Critics have argued that such emotivist models fail to adequately account for the ways in which cognitions constructed over a person's lifetime alter or enter into the regulation of affect, and final appraisal of a social situation (Pizzaro and Bloom, 2003; Turiel, 2010). Moreover, such emotivist theories misrepresent the ways in which affect and cognition are intertwined even in the case of such inborn affective response systems (Damasio, 1996). For her part Noddings (2008) disavows these reductionist and simplistic efforts to account for the role of emotion in moral functioning, and distinguishes them from the ethic of care.

Developmental Discipline

Translating the ethic of care into educational practice has fallen primarily to educational researchers who have focused upon classroom climate and developmentally appropriate modes of student discipline. The most extensively researched effort to combine classroom practices with the goal of enhancing an overall climate of trust and moral 'goodwill' (Arsenio and Lover,

1995) has been Watson's (2003, 2008) work on what is referred to as *developmental discipline*. Watson's approach integrates basic elements of attachment theory (Shroufe, 1988) with the 'self-determination theory' (Deci and Ryan, 1985) view of student motivation. A central tenet of developmental discipline is that young children need to establish sound attachment relationships with significant adults. Classroom teachers fall within this adult category and in some cases serve as surrogates for parents who have not provided these emotional needs for their own children. The basic goal of developmental discipline is to enlist children's basic attachment needs and their intrinsic motivations for autonomy to guide students toward engagement in moral conduct. Teachers employing developmental discipline minimize their use of power assertion, and focus instead on efforts to engage students in reflection on their own motivations and feelings as well as the effects that their actions have had on others. Conflicts are resolved by mediating discourse between or among students with encouragement to find their own solutions, rather than resorting to teacher-imposed resolutions. Students are also involved in the construction and/or modification of classroom rules and conventions governing their behavior. These practices are largely congruent with the positions taken by Piaget (1932) and his educational supporters (DeVries and Zan, 1994). For Watson (2003), engagement of students in the process of establishing classroom customs and scaffolding their capacity to resolve interpersonal conflicts is an aspect of community building that contributes to the overall atmosphere of trust. It is this sense of 'trust' that Watson views as critical to the developmental needs of elementary school children, and allows them grow morally (Watson, 2003). Research conducted on the effectiveness of developmental discipline on students' prosocial behavior has been largely supportive (Battistich et al., 1997). A retrospective study of young adults reported that experiences in elementary classrooms employing developmental discipline have salutary long-lasting impacts (Watson, 2008).

Social Cognitive Domain Theory and Moral Education

By the 1980s a number of questions and challenges arose regarding Kohlberg's (1984) stage theory of moral development (Snarey and Samuelson, 2008). Among the problems noted are the inconsistencies in expression of moral stage within individuals across contexts (Carpendale and Krebs, 1992), the lack of fit between the Kohlberg assessment of moral growth and the moral judgments of individuals from non-Western cultures (Snarey and Keljo, 1991), and the general lack of correspondence between moral reasoning and behavior when defined in terms of Kohlberg stage (Blasi, 1980). What emerged from subsequent developmental research are accounts that view social and moral reasoning as heterogeneous and multifaceted (Turiel, 2002). The dominant post-Kohlberg paradigm for research on moral development is what is referred to as *social cognitive domain theory* (Smetana, 2006; Turiel, 2002). According to domain theory concepts about morality emerge in early childhood around nonarbitrary and universal considerations of acts such as hitting and hurting that have consequences for others. Moral judgments are structured by underlying conceptions of fairness and human welfare, and are distinct from concepts about social conventions that are the contextually dependent and agreed upon social rules established through consensus by members of a given social system or group (Turiel, 1983). Over the past 30 plus years numerous studies conducted in a wide range of cultural contexts have replicated the basic finding that children and adults maintain conceptual distinctions between issues of morality and societal convention (Turiel, 2002; Nucci, 2001). The youngest age at which children have been reported to reliably distinguish between morality and convention is 2 ½ years (Smetana and Braeges, 1990). Most recently, it has been discovered that this basic distinction is maintained even by children suffering from autism (James and Blair, 2005; Leslie et al., 2006). Neuroscience research has indicated that issues of morality and convention are processed differently (Lahat et al., 2012).

The domains of morality and convention are further distinguished from concepts about personal matters of individual choice and privacy (Nucci, 2001, 2014). While morality and convention deal with aspects of interpersonal regulation, concepts of personal issues refer to actions that comprise the private aspects of one's life, such as the contents of a diary, and issues that are matters of preference and choice (e.g., friends, music, hairstyle) rather than right or wrong. Research conducted in a wide range of cultures has indicated that claims to a personal area are a fundamental aspect of social development critical to the establishment of personal autonomy and individual identity (Nucci, 2001, 2014).

In contrast with the developmental assumptions of Piaget (1932) and Kohlberg (1984) in which morality gradually displaces convention as a basis for moral judgments, domain theory maintains that conceptions of morality and convention coexist as separate conceptual frameworks throughout development. Moreover, judgments made in context may draw from one or another conceptual domain (include the personal), or entail coordinations across domains as a function of the individual's interpretation of the moral and nonmoral elements of a given social situation (Smetana, 2006; Turiel, 2002). With development children construct more comprehensive and internally consistent concepts within each domain, and become increasingly capable of engaging in cross-domain coordinations (Nucci, 2009; Nucci and Turiel, 2009; Smetana, 2006).

Revised Aims of Moral Education

This more complex account of moral and social development has led to corresponding modifications in statements of the developmental aims of moral education (Nucci, 2001, 2009). The core focus of moral education remains on the development of the students' conceptions of fairness and human welfare. However, the goals also include attention to the capacities of children to coordinate moral and nonmoral considerations in context (Nucci, 2009; Nucci and Turiel, 2009). This includes supporting the construction of understandings of the function, purposes and importance of conventions. More centrally, however, this view of social and moral cognition makes it evident that children may be engaged in meaningful reflection on the moral implications of prevailing social norms and conventions at *all* points in development, and not just at the more advanced principled level of moral reasoning (Nucci, 2009). The aim of moral education is correspondingly

redirected toward increasing the capacity to manage moral complexity and the application of moral considerations of fairness and concern for rights and human welfare across the lifespan.

Educational Applications

Advocates for the application of domain theory to moral education maintain the emphasis on attention to development, but modify this principle with an attention to social cognitive domain (Nucci, 2001, 2009). Domain theory based research has largely supported the practices advocated by proponents of *developmental discipline* and the concerns for care expressed by Noddings (2002) and social justice by proponents of just community schools (Power and Higgins-D'Alessandro, 2008). For example, research on children's moral emotions sustains the emphasis on establishing a climate of *trust* (Watson, 2003) as being concordant with the child's construction of a moral worldview based upon 'goodwill' associated with prosocial moral behavior (Arsenio and Lover, 1995). What has been added is specificity with respect to the social messages teachers should convey when engaging students around moral transgressions and violations of school rules (Nucci, 2001). Research has demonstrated that children evaluate teacher responses to their transgressions in terms of their correspondence to the domain of the transgression (Killen et al., 1994; Nucci, 2001). Statements of governing rules, or teacher statements focusing upon disruptions to classroom functioning concordant with violations of conventions were rated highly by students, but were given low ratings as teacher responses when applied to moral violations. In contrast directing students to consider the consequences of actions upon the welfare of others were rated highly as appropriate teacher responses to moral violations, but not in response to violations of school conventions. Teachers who consistently employed domain inconsistent social messages were rated lower by students than domain concordant teachers. These ratings are associated with student compliance with teacher directives.

Attention to domain has also been found to impact the effective use of the academic curriculum as a medium for moral education (Nucci, 2001). This was demonstrated in a study in which high school teachers led students in discussion of moral, social conventional and mixed domain issues drawn from their high school English composition and American history courses. In one condition teachers directed students in discourse consistent with the domain of the social issues. Discussion of moral issues (e.g., slavery) centered on considerations of fairness and human welfare, while discussions around conventional issues (e.g., modes of dress) focused upon the function of social norms for establishing social order and societal structure. In a second condition teachers structured the discussion in a domain-discordant fashion focusing upon social norms for the conventional issues, and fairness and welfare for issues of convention. In a third condition the teacher simply used one or the other mode irrespective of the domain of the issue under discussion. Findings from the study demonstrated that development of students' concepts of morality and societal convention was optimal in the domain concordant condition. Moreover, only those students who participated in the domain appropriate learning context demonstrated the ability to spontaneously coordinate moral and societal considerations when interpreting and evaluating mixed domain issues involving both conventional and moral elements (Nucci, 2001).

Community Service and the Moral Self

One major challenge for moral education is translating classroom and school experiences into changes in moral behavior. One school of thought maintains that the bridge between moral judgment and action is the integration of moral judgments with the individual's moral aspects of personal identity and sense of self (Blasi, 2005; Colby and Damon, 1992). The formation of moral identity is thought merge in early adolescence as part of the more general process of identity formation in adolescence and early adulthood (Hart, 2005). Despite misgivings that have been expressed about the reduction of moral motivation to self-consistency (Nucci, 2004), one author has made a thoughtful case for the development of moral identity as the aim of moral education (Lapsley, 2008). The vehicle that has gained most attention as having potential for impacting moral identity and behavior has been the extension of school-based social experiences to include community service activities (Hart et al., 2008).

Efforts to promote youth engagement in community service are not new, and can be traced back in the United States to William James who regarded service to the broader community and nation as the 'Moral Equivalent to War' (Killen and Horn, 2000). When community service is linked to the school curriculum in the form of mandated requirements it is given the label 'service learning.' Programs for service learning are diverse and include a range of activities from tutoring or coaching youth sports to working in a community soup kitchen. For this reason the impact of service learning has been somewhat difficult to evaluate. Nonetheless, some conclusions have begun to emerge indicating that well-run service-learning programs lead to an increased level of civic engagement (Andersen, 1998; Hart et al., 2008; Youniss et al., 2001; Youniss and Yates, 1997), and are associated with an increase in positive moral action and a decrease in rates of delinquent conduct (Hart et al., 1998; Hart et al., 2008).

At least two factors appear to be important for service learning to positively impact students' social growth. The first is that some degree of choice as to the nature of the particular activity a student will take part in seems to be important for the activity to have positive benefit (Andersen, 1998; Barker and Eccles, 1997; Nucci, 2001). The importance of choice is linked to student motivation as well as identity formation. In this regard, Leming (Nucci, 2001: p. 214) reported that when programs force students into so-called 'voluntary' service activities, they result in alienation among adolescents who see through what they perceive to be blatant attempts by schools to make them into particular sorts of people.

The second critical factor is that the service-learning activity be linked to a period of reflection (Andersen, 1998; Youniss et al., 2001; Youniss and Yates, 1997). The degree of reflection varies from program to program from such minimal activities as writing a one-page reaction paper to keeping a daily journal (Killen and Horn, 2000). The importance of reflection rests on

the opportunities it affords for students to share feelings and experiences and to connect those experiences to their own social values and sense of self (Andersen, 1998). Killen and Horn (2000) suggest that such reflection engages students in considering issues of fairness and social inequality that foster moral growth, and may also touch upon consideration of the ways in which conventional stereotypes constrain outgroups such as the poor and disabled. Opportunities for reflection upon service activities may also engage students in discovering one's connections to others and concomitant sense of responsibility and efficacy (Killen and Horn, 2000). Finally, it has been proposed that the effectiveness of 'service learning' to foster the connection between moral actions and personal identity stems from the student's own reflection upon the ideological assumptions of service agencies, and the moral impact of service activities in relation to the values maintained by the individual student (Youniss et al., 2001; Youniss and Yates, 1997).

Conclusions

Since the 1930s the research on children's moral development has guided moral education and promoted it as an alternative to traditional forms of character education. Recent research has shown that such traditional efforts are largely ineffective at impacting attitudes and behavior above the effects of widely recognized 'best teaching' practices that emphasize classroom community, student intellectual autonomy, and high levels of academic instruction (Social and Character Development Research Consortium, 2010). The research on moral and social development has supported the general contention that moral education requires attention to students' construction of moral and social judgments and not solely the acquisition of societal standards or 'virtuous' habits. This recent work indicates that moral concerns for justice and human welfare are available from early childhood and forms the focal point for moral education. At the same time, however, current research indicates that moral development does not move toward an end point where moral principle triumphs over nonmoral considerations. Thus, moral education requires a variegated approach to preparing students to handle moral complexity with respect to personal behavior and efforts to construct a just and compassionate society. Finally, recent work has suggested that education for moral development should also include experiences beyond the classroom that engage students in activities connecting them in substantive and personal ways with the broader community.

Moral Development, Cultural Differences in

Klaus Helkama and Florencia M Sortheix, University of Helsinki, Helsinki, Finland

Abstract

Drawing on current conceptualizations of values (Schwartz's basic human values theory) and the moral domain (Haidt's moral foundations theory; Shweder's big three of morality), as well as the cognitive developmental approach to morality, we examine research on cross-cultural differences in the emphases on different parts of the moral domain and in the pathways of moral development in the light of cultural variations in wealth, relatedness, and hierarchy. We also review studies of age-related changes in values and justice-oriented reasoning, and examine influences on cultural and individual inclusiveness of the moral ingroup.

The Moral Domain

Morality has two functions: to promote ideals and justice, and to maintain social stability. Among the classics in psychology and sociology, Piaget and Weber stressed the former, Freud and Durkheim the latter function. The current dominant definition of the moral domain (Haidt, 2012) includes six moral foundations: harm/care (not hurting anybody, caring for the weak), liberty (freedom from oppression), fairness/reciprocity (equal treatment of all), ingroup/loyalty (not betraying one's group, being proud of the history of one's country), authority/respect (showing respect for authority), and purity/sanctity (not violating standards of decency). The first three foundations are, roughly, related to the promotion function of morality, the three latter to its prevention function. Another taxonomy of moral ideologies is Shweder et al.'s (1997) 'big three': Ethic of autonomy (corresponds to Haidt's care, liberty, and fairness), community (ingroup and authority), and divinity (purity). Obviously, the foundations could be in conflict, for instance, in a choice between ingroup loyalty and honesty. In line with the two opposite functions of morality, politically conservative people in the United States emphasize the three foundations related to stability (loyalty, authority, and purity), whereas liberals stress the change-oriented harm and fairness foundations.

Values, abstract, general, desirable goals, represent what is most important in life. They are the foundations based on which people live and relate to others (Schwartz, 1992). Studies relying on Schwartz's (1992) value model suggest that there is also universal agreement that some values are moral. His model postulates 10 universal values. They can be described in terms of a circular structure with two dimensions, self-enhancement – self-transcendence and conservation – openness to change. Values relate in consistent ways to moral foundations (Boer and Fischer, 2013). Benevolence is regarded as a moral value in widely different cultures (Vauclair, 2010), and is positively associated with all five moral foundations among more than 34 000 respondents from all over the world (Graham et al., 2011). Conformity and tradition-related values (self-discipline, politeness, honoring of parents and elders; being devout, respect for tradition) are related to the two foundations of authority, and purity (Boer and Fischer, 2013), possibly also to ingroup (Sverdlik et al., 2012), see **Table 1**.

Except for benevolence, the moral domain varies across cultures. Conformity and tradition are more often regarded as moral values in less wealthy than in affluent countries, whereas universalism values (e.g., broadmindedness, equality, world peace, social justice, protecting environment) and even some self-direction values (freedom) are regarded as moral values more often in wealthy individualistic than in poor collectivistic countries (Sverdlik et al., 2012; Vauclair, 2010).

Morality is neither sociologically nor psychologically a coherent system. Max Weber pointed out in 1918 that our conceptions of justice involve a fundamental antinomy or incompatibility, between egalitarianism and merit. Neuropsychological research shows that we regard it as right to kill one person by turning a switch in order to save five people, but regard it as wrong to kill one person by pushing him from a bridge to save five persons. The thought of pushing another activates the 'old' regions in our brain, whereas the thought of turning the switch activates the 'new' parts of the brain.

However, there are universally shared moral intuitions, for instance, that dishonesty is wrong. Vauclair and Fischer (2011) reviewed responses of more than 200 000 people from 84 countries to the 'morally debatable behaviors' scale, used in the World Value Survey since 1981. By means of multilevel analyses they found that there was very little variation across cultures or across individuals in the opinion that such 'dishonest and illegal' acts as accepting a bribe were wrong. By contrast, there was a great deal cross-cultural as well as within-culture variation with regard to 'personal and sexual' acts like abortion, homosexuality, or divorce.

Table 1 The moral domain in different psychological approaches

Schwartz's values	Self-direction, universalism, benevolence	Conformity	Tradition
Haidt's Moral foundations	Liberty, fairness, care	Ingroup/loyalty, authority/respect	Purity
Schweder's 'big three'	Autonomy	Community	Divinity

Moral development is here defined as any change in a morally relevant psychological variable that occurs in human beings as they age. Culture is here seen as the primary mode of human adaptation, which reflects the demands of the ecological, demographic, and institutional environment, as well as historical experiences. Culture and development are intertwined in many senses. Culture sets the developmental tasks for individuals and largely defines developmental pathways of development.

A hunting and gathering culture is egalitarian and low in conformity, often with benevolent attitudes to outgroups. A culture adapted to an agrarian socioeconomic environment is organized by the dimension of relatedness, where the individual is part of the social system, defined by cooperation, acceptance of hierarchy, striving for harmonious relationships. A culture, adapted to an urban socioeconomic postindustrial environment, is organized by the dimension of autonomy; the individual is self-contained in a social system defined by a mixture of competition and cooperation, and plurality of values. We examine sociocultural contexts that range from countries and geographic areas to smaller units such as professions or families. In characterizing those contexts, the focus will be on the dimensions of relatedness – expressed by autonomy vs. embeddedness (Schwartz, 2008) – and hierarchy – egalitarianism (expressed by Schwartz's and Hofstede's well-known dimensions) as well as economic affluence of the social unit.

Pathways of Moral Development

As the moral domain varies cross-culturally, so do pathways of moral development. This is seen already in infancy. In cultures where relatedness values (conformity, tradition) are emphasized, socialization goals and parenting strategies of mothers for their infants differ from the goals and strategies of mothers in postindustrial cultural contexts (Keller, 2007). There is no explicit developmental cross-cultural research on the authority, ingroup, and purity foundations. Jensen (2011) advanced a cultural–developmental theory, in which she outlined a series of developmental trajectories for the autonomy, community, and divinity in different cultural contexts. She noted that community-related arguments increase with age, as shown by the findings that in late adolescence and adulthood, there is an increase in moral concepts associated with societal organization, and with what is best for the society. These results are found not only in western countries, but also in India and Zambia. Adulthood age trends from representative national samples are consistent with this view, as they demonstrate an increase in the importance of conformity and security values.

Wealth has two important consequences for values and moral development pathways. First, it increases the likelihood of individualism and democracy (causality is reciprocal). Inglehart and Welzel (2005) found that the ratio of societal changes toward democracy vs. changes toward autocracy for the period 1950–90 increased with wealth. In countries with per capita incomes greater than 7000 dollars, changes toward democracy occurred 28 times as often as the reverse changes. Even within democracies, wealth increases preference for fairness and care (self-transcendence values). Van Herk and Poortinga (2012) examined 195 regions in Europe comparing the influence of historical factors and current economic situation. They found that contemporary affluence, measured by the gross national product (GNP), was far more important than history in explaining preference for self-transcendence values (benevolence and universalism). Using the third wave of the European Social Survey, we calculated correlations of universalism with age. Despite the confounding of cohort effects, correlations were positive in all countries, ranging from 0.12 (Denmark) to 0.31 (Russia). Democracies, then, seem to favor the moral developmental trajectory toward universalism values.

A second consequence of wealth is increasing value differentiation (Boer and Fischer, 2013). In wealthier and more individualistic societies, there is less value consensus. Schwartz and Sagie (2000) suggest that with increasing democratization, value consensus further decreases. This means that a new developmental task emerges: how to solve value conflicts? That is the focus of Kohlberg's (1984) cognitive–developmental theory of moral judgment.

Kohlberg's Theory of Moral Development

The cross-cultural studies on Kohlberg's developmental theory of moral judgment are far more numerous than on any other approach (see, e.g., Eckensberger and Zimba, 1997). His basic focus was moral judgment, which is the ability to reason about value conflicts. He attempted to formulate a system of universal moral categories. Kohlberg's category system covered, broadly, Haidt's (2012) six foundations. In Kohlberg's Moral Judgment Interview (MJI), two commonly accepted moral principles clashed in a dilemma, for instance, saving a life vs. obeying the law, or authority vs. honesty (promise keeping).

Moral development was defined by the justifications (structure) people gave for their choices, not by the choices (content). The justifications were rank ordered into stages according to their cognitive sophistication and level of social perspective taking. Thus, the criteria of development were more stringent than mere age-related change. After a radical revision of the scoring system, the final sequence consisted of five empirical stages (preconventional: (1) heteronomous morality, punishment, and obedience to authority; (2) individualism, instrumental purpose, and exchange; conventional: (3) mutual interpersonal expectations, relationships, and interpersonal conformity; (4) social system and conscience; and post-conventional: (5) social contract or utility and individual rights).

Although Kohlberg initially thought that development would lead to agreement on universal ethical principles at Stage 6, this stage was not found in empirical studies. At the post-conventional level, there is no value consensus but post-conventional arguments could be employed to defend a variety of values. While research has supported many Kohlbergian criteria of development, e.g., the hierarchical nature of the stages, there is more situational variation in the arguments than Kohlberg's idea of stages as integrated wholes implied. Therefore, current usage relies on the concept of a schema: personal interest schema for Stage 2/3, maintaining norms

Table 2 Developmental approaches to morality

Fairness
Kohlberg (1984): Stages of moral reasoning
Focus: Solving value conflicts presented in hypothetical dilemmas
Methods of assessment:
- Moral Judgment Interview (MJI; Colby and Kohlberg: The measurement of moral judgment, Cambridge University Press, 1987; production measure)
- Defining Issues Test (DIT; Rest: Development in judging moral issues, 1979: comprehension and preference) DIT-2 (Rest et al., 1999)
- Sociomoral Reflection Measure (SRM; Gibbs, Widaman, and Colby, Child Development, 1982)
- Sociomoral Reflection Measure-Short Form (SRM-SF; Gibbs, Basinger, and Fuller, Moral maturity: measuring the development of sociomoral reflection, Erlbaum, 1992). (The SRM-SF, unlike the other instruments, is not based on dilemmas.)
- Moral Judgment Test (MJT; assessment of moral arguments); Lind (www.uni-konstanz.de/ag-moral/lind.htm)

Care
Gilligan: In a different voice (1982)–Skoe (1998): Ethic of care
Focus: Solving dilemmas on care of others vs. care of self (partly own real-life dilemmas)
Countries: Norway, Canada, Finland (Juujärvi, Myyry, and Pesso, J. Moral Education, 2010)
Method of assessment: Ethic of Care Interview (Skoe et al. Early Adolescence, 1999)
Eisenberg et al. (Developmental Psychology, 1987): Prosocial reasoning
Focus: Reasons for prosocial behavior
Countries: USA, Brazil (Eisenberg, Zhou, and Koller, Child Development, 2001)
Method of assessment: Prosocial dilemma interview

Community, autonomy, and divinity (the 'big three')
Jensen: Coding manual for the ethics of autonomy, community, and divinity (2004).www.LeneArnettJensen.com
Focus: Coding moral reasons from moral discourse
Guerra and Giner-Sorolla: Community, Autonomy, Divinity Scale (CADS), Journal of Cross-Cultural Psychology, 2010

Moral exemplarity
Studying morally outstanding persons who have shown extraordinary commitments promoting benevolence, justice, or basic human welfare (Life review interview; List of personal strivings; Frimer, Walker, and et al., Journal of Personality and Social Psychology, 2011)

schema (Stage 3/4), and postconventional schema (Rest et al., 1999).

Most importantly, there is empirical support for the assumption that higher stage solutions to moral problems are felt to solve those problems in a more balanced and just way. When presented with Stage 5 postconventional arguments and Stage 4 conventional arguments, both right-wing and left-wing students in Britain prefer Stage 5 to Stage 4. High scorers are less self-serving in judging their own and others' bad deeds and more likely to rely on the procedural justice principle of bias suppression in reporting personal real-life dilemmas (Myyry and Helkama, 2002). However, high scorers are hardly more likely to resist temptation or show altruism or moral responsibility than others.

Kohlberg's theory conceptualizes environmental influence in terms of social perspective-taking opportunities (participation in peer groups, decision making in the family, and sense of participation in societal institutions of work and politics in general). These experiences stimulate the growth of justice reasoning. The structural nature of the stages implies that development is mainly about increasing sophistication, i.e., differentiation and hierarchical integration of moral concepts, as well as increasing universality, but does not necessarily lead to adoption of any definite values.

The variety of approaches and measures of different aspects of moral development are summarized in Table 2. Findings on comprehension and preference formed the basis of Rest's Defining Issues Test (DIT), which measures the preference for postconventional schema and has been frequently used in cross-cultural research. Gibbs's measures, on the other hand, deal with development up to Stage 4.

Is there evidence for the Rousseau-derived hypothesis of a 'natural' universal trend toward postconventional Stage 5 judgment? Studies carried out with the MJI, where respondents produce moral arguments, show that Stage 5 is extremely rare (Eckensberger and Zimba, 1997; Snarey, 1985). By contrast, studies that have used the DIT, a comprehension and preference test, suggest that the preference for postconventional arguments increases with age and education in a number of countries (Gielen and Markoulis, 2001). The postconventional schema reflects an outside-society or prior-to-society perspective, as illustrated by such items of the DIT as "would (X) in this case bring about more total good for the whole society or not" or "what values are going to be the basis of governing how people act toward each other."

Social perspective taking has been shown to be the factor underlying the progress along the stages of justice reasoning judgment, irrespective of method of assessment (Gibbs et al., 2007). The same holds for the ethic of care. Therefore, when looking at culture-based differences in Kohlbergian moral development, the natural question is: What are the dimensions of culture that are related to social perspective-taking opportunities and actual perspective taking?

Culture-Based Differences in Justice Reasoning

The prototypes of Gesellschaft (society) and Gemeinschaft (community) have been used as explanatory constructs for cultural differences in the attainment of higher stages (Snarey, 1985). Gesellschaft, an urban, complex, heterogeneous environment, with a variety of contacts with strangers, supposedly provides more varied social perspective-taking opportunities than does Gemeinschaft, rural, face-to-face, homogeneous environment, where contacts are mostly with familiar people. Movement of any ecological variable (e.g., diversity of occupations or formal schooling) in a Gesellschaft direction shifts cultural values toward more individualism and developmental pathway toward more independent behavior (Greenfield, 2009).

However, in addition to a movement toward a larger society (Gesellschaft), the cultural value of autonomy vs. embeddedness could be related to perspective taking. One prerequisite of social perspective taking is the existence of value plurality, which means increasing likelihood of encountering situations where different values are represented by different people, i.e., in a sociocognitive conflict. Experimental studies show that sociocognitive conflict leads to cognitive development. In autonomous societies individuals are socialized for independent thinking and personal freedom is highly valued. In more

embedded societies religion, group norms and social conventions govern everyday life giving less freedom for individual choices in moral justice-oriented reasoning. The weaker value consensus in more democratic societies implies that individuals growing up in such societies are more exposed to sociocognitive value conflicts, so we could expect that they score higher on moral judgment tasks.

The role of egalitarian vs. hierarchical cultural values also seems to influence moral development. Hofstede's power distance (hierarchy) refers to the extent to which those lower in organizational hierarchy regard inequality as natural. **Table 3** shows that moral judgment development scores tend to be higher in countries which score lower on power distance. The upper half of **Table 3** shows the scores for the highest scoring (higher middle class) adults in Snarey's (1985) review of studies using the Moral Judgment Interview, and the bottom half shows the *P*% (percentage of postconventional arguments regarded as most important) scores of freshman samples from different countries in Gielen and Markoulis' (2001) review, with Spearman rho = 0.80 ($p < .01$). The notable exception from the pattern in **Table 3** is Ireland, low in power distance but also low postconventional morality. This is probably due to the influence of Catholic Church.

Religious orthodoxy is associated with lower postconventional scores (Rest et al., 1999). Where a high proportion of moral rules are seen as absolute, there is less room for value conflicts.

The role of egalitarianism is also seen in smaller cultural units; e.g., families. Adolescents who participate in decision-making score higher on the DIT than adolescents in hierarchical role–oriented families. Husbands and wives who make decisions together score higher on the MJI than those who do not. Although these findings could be due to the tendency of individuals high on justice-oriented reasoning to act democratically, the findings on university students' moral judgment development suggest that the causal link goes from a hierarchical culture to individuals.

The US business world is hierarchical, and the business students score lower than expected on measures of moral reasoning (Maeda et al., 2009). Also the medical profession is known to be fairly hierarchical. In contrast to students in other fields of study, European and Canadian medical students do not appear to progress on moral judgment. This is suggested by findings of regression in at least four recent longitudinal studies, which used different Kohlbergian methods to assess justice-oriented reasoning. Presumably, for the medical profession, like other life-and-death occupational groups (fire brigades, armies), a hierarchical organization is often a natural one for effective functioning. Solving value conflicts is not easily compatible with its functional requirements. However, the hierarchical organization of medical profession and its consequences on moral reasoning is no natural law, as shown by findings of clear progress among medical students in the United States (Maeda et al., 2009). Likewise, business school students in Finland obtained high scores on postconventional moral judgment in the 1980s.

Over the past decades, inequality has increased almost everywhere in the Western world. The findings that in the United States, university students' *P*% scores have declined, narcissism increased and empathy decreased are consistent with each other in suggesting a weakened disposition of taking into account the feelings and consequences of own actions for other people.

Democracies provide a sense of participation in the political process, an essential input for the attainment of the system perspective and the prior-to-society perspective, on which

Table 3 Moral judgment development indices and power distance

Egypt	22.6	80

MMS; moral maturity score.
P% = weighted percentage of postconventional arguments ranked among the most important ones.

Kohlberg's Stages 4 and 5 are based. On the other hand, a substantial proportion of citizens with the Stage 4 and 5 systems and prior-to-society perspective seems to be a prerequisite of a well-functioning democracy. These perspectives enable them to see the common good in the midst of competing values and ingroup as well as religious loyalties. To summarize, Gesellschaft (as opposed to Gemeinschaft), autonomy (as opposed to embeddedness), brought about by sufficient wealth, as well as democracy and egalitarianism in the sense of low power distance (as opposed to autocracy, hierarchy, and high power distance) seem to be those dimensions of culture that are conducive to individual development of justice-oriented reasoning.

Other Developmental Dimensions

After Kohlberg, several moral–developmental dimensions have emerged (Table 2). Far less cross-cultural research exists on these dimensions than on Kohlberg's justice. An attempt to build a comprehensive moral–developmental psychology, relying on neo-Kohlbergian findings and brain research is Narvaez's (2008) Triune ethics. It unites findings from brain and clinical research with studies of moral emotions, and singles out three basic ethical mindsets, which represent global brain states. Ethic of safety, shared with all animals, is based primarily on instincts for survival, and located in the brainstem and lower limbic system. Ethic of engagement is based on mammalian emotional systems that guide people toward intimacy, as e.g., in parental care, or play in a peer group. Ethic of imagination relies on recently evolved parts of the brain (neo cortex and prefrontal cortex) and makes possible will power as well as moral problem solving by means of reflection. How much one favors one mindset over another is shaped by experience in early life (i.e., caregiving practices) and other sensitive periods.

Moral Values and Development of Justice-Oriented Reasoning

If the structural development of moral judgment does not lead to agreement about the hierarchy of moral principles or moral values, then it is natural to ask how value priorities and moral judgment development are related. Few associations of value priorities with Kohlbergian moral development have been published, which is consistent with the idea of the independence of structure (moral stage) and content (value). A review (Helkama, 2011) found that 70% of the 24 significant positive associations of Kohlbergian measures with values were for universalism values, and the rest were evenly divided between benevolence and self-direction.

Conformity values have shown negative correlations with Kohlbergian measures of moral development in educationally homogenous samples. Universalism values are by definition universalistic in the sense of being related to concern and protection for the welfare of all people and nature. Benevolence and conformity are ingroup values, concerned with the welfare of close ones and restraint from violation of ingroup norms, respectively. The association of universalism with the development of moral reasoning could be attributed to the close association of universalism with social perspective taking and empathy.

Moral Inclusiveness, Country-Level, and Individual-Level

The two ingroup values, benevolence and conformity, while motivationally close, relate to perspective taking and empathy differently. Across eight studies in four countries, benevolence showed consistent associations with both cognitive perspective taking and emotional empathy, while conformity did not show any associations (Helkama, 2011). The fact that the patterns in the associations of benevolence and universalism are very similar – almost identical – could be used to argue that universalism could be understood as sympathy extended beyond the boundaries of the ingroup, to all people. This idea is supported by the notion of the inclusiveness of the moral universe (Schwartz, 2007), which is defined as the extent toward which universalism values are applied to outgroup members. At the country level, inclusiveness increases with egalitarianism and democratization and decreases with embeddedness.

Schwartz (2007) operationalized the notion of the inclusiveness of moral universe by looking at the separation of benevolence and universalism values from a psychometric point of view. He took as his starting-point four universalism values, broadmindedness, equality, social justice, and a world at peace. If all four items were intermixed with benevolence or other moral value items, the inclusiveness score was 0, and if all of them formed a distinct region, then it was 4. Among 66 countries, democratization was the strongest predictor ($r = 0.73$) of inclusiveness. In a sample of 21 European countries, inclusiveness of moral universe predicted acceptance of immigrants. Moreover, the country inclusiveness moderated the associations of universalism with acceptance of outgroup immigrants and participation in prosocial activity, so that the association was stronger in those countries where moral universe was more inclusive, i.e., where universalism values were understood as applying to members of outgroups, too.

The inclusiveness of an individual's moral ingroup should increase with his or her moral judgment level, if Kohlberg's stages follow the Kantian notion of universality, as he assumed. Because history provides many examples of members of highly developed cultures whose belief in their moral superiority has led them to barbarous acts toward outgroup members, it is appropriate to ask whether and when high scores on Kohlbergian measures of moral judgment predict inclusiveness of the moral ingroup. Two studies seem relevant.

One study (Helkama, 2009) examined opinions about development cooperation in relation to Kohlberg's moral stages at two points of time among ordinary adults in a Finnish rural community. When economy was thriving (1982), moral judgment level predicted inclusiveness of the moral universe in the sense that those who scored higher on moral judgment were more likely than low scorers to see contributing to development cooperation as a moral duty. However, during the massive economic recession in 1993, no association was found between moral reasoning and inclusiveness of the moral

ingroup, defined in terms of the same questions on development cooperation. The inclusiveness of the moral universe in that specific rural community in 1993 was much narrower than the Finnish average over 1990s. Thus, the relation of moral judgment development to the inclusiveness of the moral ingroup varies as a function of the economic situation.

The other study (Passini, submitted for publication) addressed ordinary Italians, who were given Rest's DIT and measures of social distance tapping prejudice toward immigrant groups. There were two kinds of dilemmas on the DIT. In some dilemmas, the protagonist was Italian, an ingroup member, in others, Romanian, an outgroup member. Overall, the postconventional score was related to lower prejudice. However, respondents with a narrow moral ingroup (i.e., prejudiced ones) scored lower on postconventional reasoning when the protagonists were Romanian (outgroup members) than in case they were Italian. By contrast, those respondents with an inclusive moral ingroup obtained identical *P*% scores on both types of dilemmas. Inclusiveness of the moral ingroup at the individual level is, accordingly, not reducible to the developmental level of moral judgment.

In sum, these studies suggest, first, that the value choices that higher stage moral arguments justify are susceptible to prevailing value climate and that the inclusiveness of the ingroup may regulate the social perspective-taking process. Categorizing some people as members of the outgroup leads to switching off empathy toward them (Demoulin et al., 2009). Second, they suggest that the inclusiveness of the moral ingroup may vary quickly as a function of the economic situation. Disease stress as well as economic threat narrow the boundaries of the ingroup and increase the importance of conservation values. In the Finnish rural community just mentioned, both local and national identifications increased from 1993 to 2007, simultaneously with the increase in importance of conservation values (Sortheix et al., 2013).

These Finnish observations, then, suggest that societal moral code adapts to economic and other threats by shifting toward relatedness values and narrower ingroups. As value consensus increases, moral judgment in the sense of ability to solve value conflicts is less needed.

Conclusions and Future Directions

The concept of moral development, introduced by Piaget and Kohlberg, is an Enlightenment notion, based on common human nature and equality of all people. The centrality of benevolence values in morality and increase in reasoning about societal organization with age seem to be universal features. Piaget and Kohlberg assumed that there is a 'natural' trajectory of development, which is only diverted by poor institutions. Rousseau's idea of a free and egalitarian society is consistent with observations on hunter-gatherers, who live in an ecological environment where autonomy is needed and equality is functional. By contrast, in conditions with high disease stress and economic scarcity, hierarchy is functional, and the authority, ingroup loyalty, and religious purity (social-stability maintaining) components of morality concur in promoting self-discipline. Increase in economic affluence decreases the need for conformity and creates pressure toward individualism, democracy, and equality. While the weight of conservation values in morality is reduced, no value consensus on universalism (fairness) along the lines of 'natural' Rousseau-like development is observed in wealthy societies, but increased value diversity, also among moral values. 'Human nature' seems equally inclined to believe in ingroup superiority and ingroup loyalty as in the Golden Rule and universal human rights. The moral–developmental trajectory for citizens in postindustrial democracies is characterized by growth of reflective moral problem-solving skills, based on social perspective taking; i.e., the developmental trajectory described by Kohlberg's stage sequence.

Moral change follows the route predicted by Bardi's and Goodwin's (2011) theory of value change: With increase in wealth and societal equality, the domain of moral values moves along Schwartz's circle from conformity toward universalism and even self-direction. In affluent contexts, ingroup norms, which in less affluent environments are all regarded as moral, get differentiated into conventional and moral ones. As the increase in wealth makes democracy and value plurality more likely, also self-direction values (liberty) become to be thought of as moral values.

While the above review suggests that moral codes tend to be rational given the life circumstances (self-discipline is stressed in conditions of scarcity, universalism in affluent societies, which can afford it), continuity of traditions is a force that is obviously also at work. Wealth does not automatically bring about individualistic values and democracy. As Boer and Fischer (2013) show in their review, the increased opportunities that arise from wealth only give rise to more choice through a cultural emphasis on autonomy (as opposed to embedded and traditional societies) and, we would add, egalitarianism. The possibility of choice (value plurality) is important, but so is the responsibility that egalitarian societies foster in their citizens (see Helkama, 2011).

With decrease in wealth, increase of threats in the environment, or increase in inequality, moral change goes to the opposite direction, as illustrated above: Universalism values become less important and conservation values more important. Since moral judgment (in the Kantian and Kohlbergian sense of ability to solve value conflicts) is less required, level of moral judgment goes down. Possibly, in these contexts the responsibility of making such choices is left to the collective or the authority.

The cross-cultural study of moral development has been fairly one-sided in many ways. Most of it has been carried out starting from Kohlberg's theory. Developmental studies have been restricted to care and fairness. In the future, there is a need for more research using other methods than questionnaires or interviews about hypothetical situations. Mixed-method approaches that combine qualitative and quantitative approaches will become more common.

Brain research is one of the most rapidly expanding areas in psychology. Integrating results from these studies (like Narvaez's (2008) Triune Ethics) with cross-cultural data will increase our knowledge of the interaction of affective and cognitive factors in moral development as well as of long-term influence of childhood experiences.

The accumulation of representative databases from earlier time periods and development of more sophisticated

statistical techniques like multilevel modeling make it possible to better understand the short-term historical and temporal dynamics of societal and psychological change in moral development and, e.g., the interplay of normative and value regulation.

The increased heterogeneity of societies implies increase in the number of people who simultaneously belong to groups that differ in their values and moral outlooks. As Sverdlik et al. (2012) point out, one important future direction is to find out how membership in multiple ingroups could be translated into a permissive moral outlook.

Abstract

Socialization approaches and cognitive-developmental theory have provided two major approaches to studying moral development. Socialization approaches have focused on the development of conscience through guilt and internalized behavior, typically measured in terms of compliance, whereas cognitive-developmental theories have emphasized developmental changes in moral judgments and reasoning. While important differences persist, contemporary approaches have attempted to integrate thoughts, emotions, and behaviors and have stressed the importance of social interactions. The rise of evolutionary based accounts have led to more research with infants and studies incorporating neuroscience, furthering the understanding of the complex nature of moral development.

Introduction

For most of the past century, much of the psychological theorizing and research on moral development has stemmed from two distinct traditions; socialization perspectives and cognitive- or structural-developmental approaches. These theories differ in how they define morality and in their hypotheses regarding its origins and developmental processes. In the first section, the authors describe how early theorists such as Freud, Skinner, and Piaget helped to shape the assumptions, questions, and methods of later developmental research. The authors then discuss empirical findings from the different perspectives and examine how contemporary approaches have developed from these foundations. They emphasize that traditional divisions have become less entrenched as theorists have begun to recognize the dynamic, integrative role of emotions, thoughts, and behaviors in moral development. Finally, the authors briefly discuss recent trends in moral development research from an evolutionary perspective.

Assumptions and Early Theoretical Roots

Socialization Theories

Historically, socialization theories have conceptualized moral development primarily in terms of children's internalization and compliance with adult and societal rules and requests, although they differ in their view of the role of emotions and affect in this process. Approaches emphasizing morality's affective components have their roots in the psychoanalytic tradition of Sigmund Freud. In line with his broader theory of psychosexual development, Freud believed that moral development entailed the internalization of societal standards through the child's identification with parents. This process resulted in the creation of the conscience, or the superego in Freudian terms, which functions as an internal regulator of behavior. The conscience inhibits the innate impulses and urges toward selfishness and aggression that, if left unchecked, would otherwise prevent humans from living in society. From this perspective, aversive emotions such as guilt, shame, and anxiety are thought to serve as the driving motivations for the child's successful inhibition of impulses and internalization of external norms.

Other socialization researchers have been influenced by behaviorist and learning theory principles as exemplified in the work of B.F. Skinner. Like Freud, Skinner did not distinguish between moral norms and other types of social rules or expectations. In contrast to Freud, however, Skinner postulated that moral behaviors are learned through conditioning and reinforcement. Behaviors valued by society are rewarded, while undesirable behaviors are punished. Some social learning theorists, such as Albert Bandura, incorporated cognitive processes, such as observational learning or imitation, to account for how novel behaviors could be acquired independent of reinforcements. Additionally, affective responses like fear and empathy retained a role in other versions of learning theory, although they were interpreted as stemming from conditioned responses resulting from the pairing of feelings of pleasure and pain with external stimuli such as punishment (Eisenberg, 1986).

Cognitive-Developmental Theories

Rooted in the theorizing of Jean Piaget, cognitive-developmental approaches focus on the development of children's moral judgments. These approaches view the child as active in his or her own development and constructing moral knowledge through reciprocal interactions with the environment (termed constructivism). In Piaget's formulation, the process of moral development does not simply entail internalization of external values and standards but rather is a constructive process leading to qualitative changes in children's thinking about right and wrong.

For Piaget, morality is inherently other oriented, revolving around notions of respect, fairness, and justice, and entailing an understanding of rules as serving these moral ideals. Piaget derived his theory from interviews with children about game rules and concepts such as stealing and lying, and his moral stage theory is closely tied to changes in children's social relationships and cognitive abilities. Initially, young children are characterized as premoral and having little concern for rules and obligations. Beginning in the preschool years, however, children enter into what Piaget referred to as a stage of heteronomous morality. Due to constraints in their cognitive abilities and their love and fear of parents, children at this stage hold an absolutist view of morality; the good is defined in

terms of strict adherence to external rules and authority commands, and acts are seen as wrong based on their objective consequences rather than actors' intentions. Social rules are viewed as unchangeable and absolute, leading to the belief that transgressions will be automatically punished (immanent justice). Interactions with peers and increases in cognitive and perspective-taking abilities during late childhood lead to the development of autonomous morality. Through cooperation with others, children come to separate their understanding of rules from notions of reciprocity, justice, and respect. They begin to incorporate intentions into their moral judgments and evaluate rules in terms of whether they serve to uphold moral principles. Although certain aspects of the theory have not received empirical support over the years, Piaget's attempts to define morality as distinct from rules and authority, and his emphasis on social interactions, has had a lasting influence on cognitive-developmental theories of moral development.

Empirical Moral Development Research: Then and Now

Socialization Theories

While psychoanalytic theory provided a conceptual basis for understanding the nature and origins of children's moral development, behaviorism and learning theory provided the rigorous empirical methods that were highly regarded during the first half of the twentieth century. Thus, many socialization researchers integrated ideas from Freudian and behaviorist traditions to understand how children internalized external moral norms and expectations through the creation of a conscience. Many studies examined correlations between parenting practices and measures of conscience, although experimental procedures in a laboratory setting were preferred. Moral behavior was typically operationalized as compliance with commands in 'forbidden toy' or 'resistance to temptation' tasks. Children were required to engage in various tedious activities without stopping, or to refrain from playing with, touching, or looking at attractive toys or objects in the absence of an authority figure. The underlying assumption was that children with an internalized conscience would willingly comply with these behavioral demands (Brody and Shaffer, 1982).

The most frequently employed measure of moral affect was the extent to which children felt guilty or anxious in response to a transgression. This was typically assessed through children's verbal judgments of hypothetical transgressors' feelings of guilt following a rule violation (Brody and Shaffer, 1982). Thus, conscience development was viewed primarily as the extent to which children would be able to inhibit selfish impulses, comply with societal and parental expectations – especially in the absence of authority – and experience guilt when rules were broken.

Much early research attempting to integrate psychoanalytic and leaning theories examined the effects of parenting on the internalization process. Because aversive emotions were seen as the primary motivational basis for moral development, disciplinary practices – particularly punishment – became the primary focus of research. Three types of parental disciplinary practices after a rule transgression were seen as relevant to children's moral development (Brody and Shaffer, 1982): power assertion (use of threats, force, removal of privileges), love withdrawal (nonphysical displays of anger or disapproval, threats of abandonment), and induction (parental explanations and reasons for why the behavior was wrong or undesirable). A consistent finding is that parents who use reasoning and induction have children with more advanced conscience development, whereas love withdrawal and power assertion were either unrelated or negatively associated with moral internalization. This was thought to be because these more punitive discipline techniques led children to develop a concern with the anticipation of rewards and punishment, which establishes an external rather than self-regulated moral orientation. In contrast, induction facilitates moral growth by focusing the child on the consequences of actions for others. In turn, this leads to a healthy sense of guilt and compliance to demands, even in the absence of an authority figure or threat of punishment.

Many contemporary socialization researchers have continued to define moral development as a process of internalization and self-regulation, yet they have shifted their attention to underscore the bidirectional nature of the parent–child relationship and the active role of the child. For instance, Joan Grusec and her colleagues (Grusec et al., 2000) have pointed out that parents' influence on children's acquisition of moral values depends on a number of additional factors, including children's characteristics and reactions to parental socialization attempts, the broader history of the relationship, and the specific socialization goals and practices parents may have in a given situation. Furthermore, while conscience continues to be defined and measured by behavioral compliance and aversive emotional reactions, Grazyna Kochanska and Ross Thompson have also incorporated positive emotions (e.g., empathy), moral cognitions (e.g., an awareness of the rules and the consequences of transgressions), and concepts such as self and identity into their conceptualizations.

Toddlers who are securely attached and in relationships with parents characterized by high levels of responsiveness, warmth, and shared positive affect show greater internalization and more advanced conscience development (Kochanska and Aksan, 2006). These early parent–child relationships are thought to provide the motivation for children to willingly and eagerly cooperate with the caregiver's socialization attempts, an orientation referred to as committed compliance. In contrast, children of insensitive parents, who share few positive and mutually enjoyable activities with their child, are more likely to induce situational compliance, or compliance that is motivated and sustained by parental pressure and fear of punishment. Likewise, mothers who elaborate more when talking with their children and who emphasize others emotions, thoughts, and perspectives rather than rules when discussing past behaviors have young children with more advanced conscience development and moral reasoning (Dunn, 2006; Laible and Thompson, 2000). Furthermore, these early relational experiences and children's committed compliance during toddlerhood are associated with more mature conscience development later in life.

Researchers also have focused on the role of temperament in moral development. Negative emotional arousal (i.e., anxiety and guilt) and the ability to regulate and inhibit one's

behavior are thought to be important for moral internalization and conscience development. Two different temperamental factors – fearfulness and effortful control – have been identified as critical, albeit in different ways (Kochanska and Aksan, 2006). Children who are highly fearful and shy are naturally more prone to negative emotional arousal and are more inhibited in their actions. Fearful children exhibit more guilt after wrongdoing and more compliant behavior, especially when parents use gentle, nonassertive parenting strategies that deemphasize the use of power. For these children, parenting practices that capitalize on negative emotions without causing high levels of distress are most effective for moral internalization. Fearless children, in contrast, do not exhibit feelings of discomfort after transgressions; thus, the emotional arousal presumed to motivate moral behavior is lacking. For these children, mutually responsive relationships and secure attachments, rather than parental discipline, is important for conscience development. Thus, the effectiveness of different socialization techniques depends on the characteristics of the child.

The temperamental trait of effortful control refers to children's ability to deliberately control behavioral impulses and is therefore thought to be important in the development of self-regulation. Children who are higher in inhibitory or effortful control are better able to resist temptations. As a result, they exhibit greater levels of internalized and compliant behavior throughout childhood (Kochanska and Aksan, 2006). Deficits in attentional and behavioral control also have been linked to problem behaviors, including aggression, substance use, and lower levels of moral reasoning in adolescence and adulthood (Eisenberg, 2000).

Two aspects of early conscience development, guilt proneness and regulatory control, are also important for adaptive moral functioning in later childhood. For instance, Kochanksa and her colleagues (Kochanska et al., 2009) found that 2- and 3-year-olds lacking guilt reactions to transgressions had higher levels of disruptive conduct (i.e., lying, fighting, bullying others, and disobedience) at 6 years of age, but only if they were also low in effortful control. This suggests that there may be different paths to conscience development. Children who lack the affective requirements for moral internalization may rely on their ability to consciously regulate behavior. In extreme cases, temperamental deficits in fearfulness and guilt-proneness coupled with emotional and behavioral dysregulation may contribute to the development of psychopathy, which is characterized by chronic and extreme antisocial behavior (Eisenberg, 2000).

One explanation offered for the link between conscience development and later moral functioning is the concept of a moral self. As children learn to self-regulate and comply with parental standards (i.e., committed compliance), they may come to view themselves as good individuals who adopt their parents' values and expectations (Kochanska et al., 2010). In early childhood, the moral self has been operationalized as the extent to which children see themselves as feeling bad and wanting to make amends after wrongdoing, complying with rules, and holding prosocial attitudes toward others. This internalized sense of self is thought to serve as the motivational basis to regulate and guide future behavior. Indeed, Kochanska et al. (2010) found that the moral self at age 5 years mediated the link between earlier measures of conscience and later moral conduct. Some have hypothesized that early conceptions of the moral self may provide the foundation for later moral identity development in adolescence and young adulthood (e.g., Hardy and Carlo, 2011; Kochanska et al., 2010), although these connections have yet to be tested empirically.

While negative emotions such as guilt and anxiety have been accorded a central role in socialization research, others, such as Nancy Eisenberg and Martin Hoffman, have also examined the positive affective and behavioral components of morality, including empathy and prosocial behavior. They assert that tendencies toward care and cooperation are rooted in our biological makeup. In contemporary developmental research, empathy is most commonly defined as an emotional response stemming from the perception of another's condition or affective state, reflecting what the other person is feeling (Eisenberg et al., 2006; Hoffman, 2000). Empathy is typically viewed as a relatively automatic, value-neutral emotional reaction that provides the foundation for feelings of care or concern for others, a reaction referred to as sympathy. Sympathy differs from empathy in that it does not involve feeling what the other person feels, but instead involves concern stemming from the apprehension of another's negative or distressing experience or state. Thus, while empathy may apply to both negative and positive shared experiences (e.g., feeling happy when others are happy), sympathy specifically pertains to feelings of concern, sorrow, or sadness for others. It is considered more developmentally mature than empathy.

When empathic feelings are highly intense or poorly regulated, however, they may lead to personal distress (Eisenberg et al., 2006) or empathic overarousal (Hoffman, 2000). This highly arousing, aversive negative response focuses on alleviating one's own distress rather than another's. It is therefore not seen as contributing to children's moral development.

Empathic connections to others' emotions and feelings are evident at birth. Newborn infants less than 24 h old have been shown to become upset and cry when hearing other infants cry, but not when hearing a tape recording of their own cries (Hoffman, 2000). The reflexive, global empathic reactions of infants become more sophisticated and other oriented during childhood, aided by normative advances in perspective taking and the ability to regulate emotional reactions. This has been assessed using simulated distress procedures in which adults (usually mothers or experimenters) pretend to be hurt, and children's reactions are coded. These procedures have revealed that facial (e.g., sadness), verbal (e.g., 'are you OK?'), and behavioral expressions (e.g., trying to alleviate distress) of empathic concern and sympathy increase during the second and third years of life, while personal distress reactions such as crying decline with age (Eisenberg et al., 2006).

Individual differences in temperament and parenting practices contribute to variations in empathy-related responding (Eisenberg, 2000; Eisenberg et al., 2006). Children and adults who are less prone to experience intense negative emotions and who are more capable of regulating their emotions show higher levels of sympathy and lower levels of personal distress. Parental influences on children's empathy-related responding are complex, and findings differ depending on whether physiological measures, facial expressions, or self reports are measured. In general, warm and supportive parenting,

including responsiveness, inductive discipline, and practices that help children understand and cope with their emotions are associated with greater sympathy and less personal distress.

These dispositions toward feelings of care and concern for others are important because they provide the motivation for engaging in prosocial behavior (defined as voluntary actions aimed at helping or benefitting others) and refraining from antisocial and aggressive behavior. As this suggests, children and adults who are more prone to sympathy engage in more prosocial behavior, such as donating to charity or assisting others. Those more prone to personal distress engage in less prosocial behavior, except when doing so is likely to relieve their own negative reactions (Eisenberg et al., 2006). In keeping with its definition as a neutral emotional reaction identical to another's situation, empathy – when distinguished from sympathy and personal distress – appears to show little systematic relationship to prosocial behavior.

The connections between empathy-related responding and aggression are more ambiguous (Eisenberg et al., 2006). Higher levels of empathy and sympathy are consistently associated with less aggressive and problem behaviors for older children, adolescents, and adults. However, in early childhood, greater empathic responding (including measures of both empathy and sympathy) has sometimes been linked to higher levels of both prosocial and aggressive behavior, perhaps because aggressive children are more assertive and more likely to engage in both harmful and helpful activities when interacting with others. Indeed, aggressive preschoolers who use both coercive and prosocial strategies for obtaining resources are also better able to appear more moral in their verbal responses (Hawley and Geldhof, 2012).

While much of the contemporary socialization research has focused on the development of moral affect and behavior within the context of parent–child interactions, cultural psychologists have focused on how different cultural systems provide a context for the development of moral values and codes of conduct (Miller and Bland, 2014; Shweder et al., 1987). Much early work from this perspective sought to categorize different cultures on the basis of their general orientations toward certain types of beliefs or practices. For instance, one broadly used distinction is between cultures that stress individual rights and personal freedoms (referred to as individualism and thought to pertain to North American and European societies as well as Australian and New Zealand) and those emphasizing duty, obligation, and interdependence (referred to as collectivism and encompassing the rest; Triandis, 1995).

In recent years, however, cultural theorists have begun to stress the heterogeneity that exists within cultures as well as between them, and have begun to explore the ways in which universal moral concepts such as justice and care can take on different meanings in distinct cultural settings. For instance, a series of studies by Joan Miller and her colleagues (see Miller and Bland, 2014) has shown that children and adults in both the United States and India view responsiveness to the needs of family and friends as important and desirable. However, Hindu Indian participants are often more likely than Americans to treat interpersonal and familial commitments as morally obligatory in different circumstances, which may stem from the way in which Indian culture emphasizes interpersonal duties and responsibility (*dharma*). Other researchers have also incorporated more qualitative and ethnographic accounts of cultural practices to explore how different communities socialize moral values (Fung and Smith, 2002).

Despite these theoretical advances, cultural psychologist Joan Miller has recently noted that this approach continues to assume a "fax model of cultural transmission" (Miller and Bland, 2014: p. 309), whereby children are presumed to automatically internalize the given values of their particular community fully formed. This is likely because the ideas and methods of cultural psychology emerged from disciplines outside of developmental psychology (i.e., anthropology, sociology, and social psychology), leaving cultural theorists with relatively little to say about the specific mechanisms by which cultural meanings and values are internalized within the individual. As a result, much of the cultural research to date has focused on adolescents and adults, and has had relatively little to say about developmental processes (but see Fung and Smith, 2002; Rogoff et al., 2007).

Cognitive-Developmental Theories

Consistent with Piaget, cognitive- or structural-developmental theories view moral reasoning as central to understanding moral action. Thus, behaviors such as aggression, honesty, and rule following (moral or otherwise) cannot be understood without knowing the thought process underlying them. As a result, researchers have adapted Piaget's clinical interview method to assess children and adolescents' moral reasoning. Judgments are elicited and probed in response to hypothetical stories or real-life situations to assess children's understanding.

Building on Piaget and beginning in the late 1950s, Lawrence Kohlberg (1971) articulated what became a very well-known global stage theory of moral judgment development. He proposed that individuals' conceptions of justice and rights develop through a series of six qualitatively distinct stages (grouped into three broad levels), with each successive stage representing a more developmentally and logically mature form of moral reasoning. During the preconventional level, children's moral judgments are based on concerns with obedience, punishment, and self-interest. The *conventional* level of reasoning develops during the adolescent years, and at these two stages, what is morally right is determined by interpersonal duties and societies' rules and laws. Although no longer tied to punishment, conventional moral reasoning still constitutes an external orientation because it is based on the existence of external rules and expectations, sharing similarities with Piaget's heteronomous stage. Kohlberg proposed that not until late adolescence (if at all) do individuals fully distinguish between social rules and the principles of justice, rights, and mutual respect, which he referred to as *postconventional* reasoning.

These stages were described as universally applicable to all people, and the ordering was believed to be invariant (i.e., occurring in the same sequence). Additionally, stages were described as 'structured wholes,' meaning that an individual's particular way of thinking about morality (e.g., as a conventional matter of rules and authority) would be the same regardless of the content or nature of the situation.

Researchers from the Kohlbergian tradition presented individuals with hypothetical dilemmas involving conflicts between different moral concepts, such as life, authority, duties, and obligations. The goal was to capture the organization or structure of thought underlying children's and adolescents' moral judgments and how these structures change with age and social experience. Similar to Piaget, Kohlberg believed that advances in moral thinking were tied to the development of children's logical thinking and perspective taking abilities; he described them as "necessary but not sufficient" for moral growth. Global stage theories were also used to examine other aspects of children's moral thinking, including distributive justice and prosocial reasoning.

Kohlberg's influence on the study of moral development cannot be underestimated; many of his contributions, including the need to ground psychological conceptions of morality in philosophical definitions, remain central to many contemporary approaches to moral judgment development. However, problems identified with the specifics of Kohlberg's theory led some of his contemporaries to question the validity of his assumptions. For instance, a number of critics argued that Kohlberg's prioritization of abstract notions of justice as indicating the most advanced levels of moral understanding were biased against women and individuals from non-Western cultures. While subsequent research has suggested that claims of bias may have been overstated (Walker, 2006), the notion that Kohlberg's theory does not adequately capture the complexity of children's (and adults') moral understanding has received substantial empirical support.

The social domain perspective, as articulated by Elliot Turiel, Larry Nucci, and Judith Smetana, has provided the most well-known and comprehensive cognitive-developmental alternative to global stage theory accounts of children's moral judgment development. These researchers have critiqued Kohlberg's use of complex hypothetical vignettes to study morality because they underestimate children's ability to make distinctly moral judgments. The results of numerous studies with culturally diverse samples of males and females from around the world have shown that children and adolescents distinguish issues of justice, rights, and welfare (moral issues) from more arbitrarily defined and contextually based social conventions (e.g., how to address an authority figure and what clothes to wear to school) at much earlier ages than Kohlberg's theory suggests.

In this approach, young children's judgments are typically studied in response to hypothetical stories that depict straightforward (prototypical) situations that correspond to different *domains* of social knowledge. For instance, moral domain events, such as one child intentionally hitting another, are presented in situations where they do not conflict with other types of goals, motivations, or events. Children make judgments about the act's *generalizability* across contexts (e.g., if it is OK if performed at home rather than at school or in another country) and *rule* and *authority independence* (e.g., would it be OK if there were no rules or authority forbidding it). Even preschoolers judge conventional rules and customs to be contextually relative, alterable, and dependent on authority and consensus. In contrast, moral obligations involving issues of justice, rights, and welfare are judged to be applicable across contexts and independent of the existence of authority or rules for their prescriptive force. By the early school years, children also justify their judgments about moral events with concerns for others' harm or welfare, fairness or rights, and obligations, whereas they justify conventional events with appeals to authority, tradition, social order, and cultural norms.

Social domain researchers have also examined children's understanding of self, identity, the causes and motivations underlying behavior, as well as judgments of personal issues. The latter revolve around individuals' control over one's body, privacy, and preferences and choices over issues such as leisure activities and friends. Personal issues are seen as outside the scope of moral and conventional regulation and are judged to be up to the individual to decide because they have no harmful consequences for others. Although the specific nature and content of the personal domain varies at different ages and across cultures, needs for autonomy and personal choice are seen as universal features of human development. As such, they are thought to serve as a foundation for children's developing understanding of rights and justice.

Children's experiences as victims, observers, and perpetrators of moral transgressions generate distinctly moral judgments. Observational studies in a variety of contexts, including home, day care, school, and free-play settings, show that parents and teachers focus on the repercussions of moral transgressions for victims. Adults emphasize the harm or unfairness of moral events and encourage transgressors to take the victim's perspective. Thus, caretakers amplify and direct children's attention toward the consequences of actions for others. Although adults are concerned with enforcing moral rules, many moral conflicts occur primarily between siblings and peers and are often resolved without adult intervention, especially as children grow older. Victims also respond with affectively charged reactions like crying, protests, and retaliation that serve to highlight the harmful nature of the transgressions. Beyond situations of conflict, Judy Dunn (2006) has shown that emotion understanding and positive sibling relationships and friendships are linked to greater moral sensitivity and care for others during childhood.

In contrast to moral events, authorities (and to a lesser extent peers and siblings) enforce conventional expectations, especially with young children. Authority figures are concerned with maintaining rules and social order and socializing children into the norms and customs of their social group. Thus, they respond to conventional violations with references to rules, authority commands, and the need for social order and decorum. By middle childhood, children also respond to others' conventional transgressions, although even preschool children enforce peer-initiated conventions. Moral violations have intrinsic consequences for others and therefore evoke powerful emotional responses, whereas violations of home and school conventions are typically judged to be affectively neutral.

Observations of preschoolers at home and at school have shown that in contrast to responses to moral and conventional events, interactions regarding personal issues (e.g., clothing and food preferences) often involve more tacit forms of communication. For instance, rather than giving direct commands, caregivers may offer choices, provide different options, or solicit opinions. Thus, parents and children

negotiate the boundaries of children's jurisdiction versus what authorities can legitimately regulate.

Although preschoolers distinguish straightforward moral events from other types of social norms, their moral understanding continues to develop throughout childhood and adolescence. For instance, compared to preschoolers, older children more consistently apply moral criteria to abstract moral events, such as those involving psychological harm (e.g., name calling). From early to middle childhood, moral concerns broaden from a concrete focus on harm and others' welfare to include an understanding of fairness as equal treatment. Adolescents become able to take context into account, leading to an appreciation for *equity*, or the idea that fair treatment entails a consideration of individuals' needs and characteristics (Damon, 1977; Nucci and Gingo, 2011), and they also become more attuned to issues of discrimination and rights.

The social domain perspective stresses that children's moral development also must consider individuals' thinking about both moral and nonmoral concerns as they overlap and conflict with each other (referred to as *multifaceted events*). This is important because, consistent with the notion that individuals actively strive to interpret and understand their social world, many everyday situations cannot be cleanly categorized as solely matters of morality or convention. Thus, variations in the salience of different concepts and how they become coordinated in thinking help to explain individual differences in moral evaluations.

Domain coordination has been examined in children's and adolescents' reasoning about various social issues, such as inclusion and exclusion from social groups; the development of prejudice based on race, gender, and ethnicity; children's and adolescents' understanding of rights, civil liberties, and government; the influence of cultural hierarchy and social roles on judgments of duty and obligation; parent–adolescent relationships and autonomy development; and lying and honesty in close relationships. The findings from a large and diverse body of research do not support a view of development as entailing progress toward a shared moral viewpoint, that morality overrides other types of concerns as children grow older, or that specific moral values come to be endorsed uniformly and consistently across different contexts (Nucci and Gingo, 2011). Rather, the picture that has emerged is that with age children come to hold a more complex, nuanced, and flexible understanding of morally relevant situations. They become better able to recognize and integrate conflicting moral, conventional, and personal concerns.

Charles Helwig's research on individuals' understanding of rights, laws, and civil liberties illustrates this point nicely (see Helwig, 2006 and, for examples in non-Western cultures, Wainryb, 2006). In one study, childrens', adolescents' and college students' evaluations of rights to free speech and religion were examined in different social contexts, including the family, school, and society. As early as 6 years of age, children conceived of rights as moral issues that were independent of authority and that should be upheld across cultures. However, developmental trends were found in the extent to which individuals identified and coordinated different factors in their judgments. Older adolescents and college students became more likely than younger children to believe that rights may be restricted in certain contexts. With age, children and adolescents began to consider an agent's mental competence and the possibility of negative consequences for others when deciding whether rights should be restricted. In another study, Helwig further found that older adolescents were more likely than younger participants to uphold rights to free speech and religion when they conflicted with established laws. With age, adolescents were better able to coordinate concepts of rules, social systems, and civil liberties. Thus, individuals at all ages endorse rights in some contexts but restrict them in others; there is no clear developmental trajectory toward upholding rights in all situations. Instead, there is an increased tendency with age to attend to and coordinate different factors and circumstances into moral judgments.

Consistent with other cultural psychological approaches (Miller and Bland, 2014), social domain researchers have also shown how different factual beliefs individuals hold about the world also may lead to variations in moral judgments (Turiel et al., 1991). Informational assumptions refer to individuals' descriptive understandings of reality, rather than their specific moral values or concepts, and can stem from many sources, including parents, science, and religion. They are often taken for granted (although accepted knowledge can change, such as with scientific progress), and they can vary substantially across individuals, religions, and ethnic groups or cultures. Informational assumptions are believed to lie at the heart of many moral and social conflicts. For example, individual differences in individuals' assumptions about when life begins and the definition of 'personhood' have implications for whether abortion is seen as a moral or personal issue.

Age-related changes in preschoolers' understanding of others' minds (referred to as *theory of mind*) have been examined as an important source of developmental change in children's factual assumptions about the world (Wainryb and Brehl, 2006). As an appreciation for others' mental states develops, children are more able to consider the reasons, intentions, and motivations behind moral events or transgressions. This allows them to incorporate and integrate information about contexts and situations when forming moral evaluations. Mental state understanding has also been linked to children's judgments of diverse cultures and tolerant attitudes toward other groups' practices. Thus, with age, children are increasingly able to take into account both moral and factual beliefs in evaluating their social experiences.

Recent Trends in Moral Development Research: Evolutionary Approaches

There has been an increased interest in integrating other disciplines, from neuroscience to anthropology, into the understanding of moral development. As an example, recent research has drawn on evolutionary theories to examine the foundational roots of morality in the first few years of life (Hamlin, 2013; Warneken and Tomasello, 2009). Specifically, researchers have focused on implicit social preferences and behavioral tendencies toward altruism and cooperation that are hypothesized to be innate. These hardwired tendencies or intuitions have been selected through evolution because of their adaptive value in promoting and maintaining harmony in

social groups, affording humans the opportunity to survive and flourish within large groups and societies.

Recent methodological advances have allowed these theorists to examine early moral dispositions toward care and cooperation in infancy and early toddlerhood. For instance, recent studies have used measures of looking time and play preferences to show that infants and toddlers, some as young as 5–10 months of age, already show an affinity for prosocial actors as well as a dislike of antisocial actors, even when the victims of such actions do not display any signs of distress or negative emotion. By 14 months of age, children also show proclivities toward altruistic behaviors, spontaneously giving assistance and help to others when needed, even in the absence of any tangible external rewards. Indeed, giving children tangible rewards for helping may actually lessen the likelihood that they will engage in such behaviors in the future by undermining their intrinsic motivation to help. However, this research is primarily cross-sectional and involves novel experiments in laboratory settings. Therefore, further studies are needed to understand how these early dispositions relate to moral understanding at later ages.

Evolutionary theory has also played an important role in the emerging field of moral neuroscience (for extensive discussions see Young and Dungan, 2012; Zelazo et al., 2010). Recent advances in brain scanning techniques, such as functional magnetic resonance imaging (fMRI), have allowed researchers to explore the different brain structures and patterns of neural activation associated with different moral capabilities. In fMRI studies, individuals are typically presented with experimental stimuli (e.g., depictions of intentional vs. accidental harm) and asked to give forced choice judgments (e.g., OK or not OK). Because fMRI records changes in blood flow between different brain areas over time, a large number of experimental trials are needed to ensure that participants are thinking about the stimuli. Given the methodological complexity of this type of research, reaction times are often used to argue for the relative deliberateness or automaticity of a particular judgment, and reasoning and justifications are rarely assessed. Neuroscientists have also utilized clinical populations, such as individuals with brain lesions, to examine how impairments in certain neural structures may influence moral functioning. Because of the invasiveness of neuroimaging procedures and the limited number of individuals with brain abnormalities, most moral neuroscience studies have been restricted to small samples conducted almost exclusively with adult populations. Nevertheless, this emerging body of research provides valuable insight into the underlying neural structure of morality.

There is a growing consensus that moral functioning is not isolated to one specific brain structure, but instead entails a variety of different areas associated with both cognitions and emotions. As an example, fMRI research has identified various areas within and related to the prefrontal cortex (PFC) as playing a crucial role in moral judgments and behavior. Paul Eslinger and Melissa Robinson-Long note that the PFC undergoes development throughout the lifespan and is a core element of a brain system that "mediates diverse information processing, consolidates complex types of knowledge and experience, integrates cognitive, visceral-somatic and affective streams of processing, and significantly influences behavioral self-regulation through goal direction, inhibition, decision-making, and self-monitoring" (Zelazo et al., 2010: p. 252). Consequently, there is substantial evidence that individuals with damage to areas of the PFC often show marked impairments in their moral and social decision making and increased rates of disruptive and antisocial behavior. PFC injury has also been tied to deficits in emotional arousal and effortful control, which socialization researchers have shown to be important for healthy conscience development. Psychopaths, who show low levels of guilt and empathy, high levels of antisocial behavior, and a reduced ability to distinguish between moral and conventional violations, also show abnormalities in PFC structure and activation.

Recent research has also begun to explore the neural underpinnings of empathy and prosocial behavior. A number of studies have shown that the same areas of the brain responsible for the experience of pain are also activated when individuals observe or imagine others being harmed. Studying children and adolescents (as well as adults), Jean Decety and Kalina Michalska (2010) also found age-related changes in neural activation while watching others being harmed. This suggested that empathic sensitivity to others' pain may shift with age from a basic, visceral emotional response to a more controlled, integrated process that takes into account different contextual cues and deliberative reasoning. These findings are fully in line with the developmental account of empathy offered by Martin Hoffman (2000). Similarly, prosocial behaviors, such as giving to charity, have been shown to activate regions of the brain associated with reward processing, which is consistent with the notion that evolved tendencies toward altruism and cooperation are intrinsically motivating (Warneken and Tomasello, 2009).

The importance of theory of mind understanding for making moral judgments has also been highlighted by Liane Young and Rebecca Saxe. In particular, a brain region known as the right temporoparietal junction (RTPJ) has been consistently implicated in the identification and representation of mental states such as beliefs and intentions. In one study, the researchers found that individuals displaying stronger activation in the RTPJ gave greater weight to an agent's intentions when evaluating hypothetical stories involving harm, leading to more accepting judgments of accidental transgressions. In a more direct test of this link, the researchers used a procedure to temporarily disrupt activation in the RTPJ and found that disrupting activation in this region led individuals to focus more on an act's outcomes (as opposed to intentions). This led them to be more forgiving of situations where agents intentionally tried but failed to cause harm to others. Similar activation of brain regions associated with mental state understanding was found by Decety and Michalska (2010) when participants viewed others intentionally – but not accidentally – harmed.

While moral neuroscience research has the potential to greatly expand the understanding of the neural processes implicated in the sense of right and wrong, the current methodological limitations preclude any strong conclusions regarding the nature of children's moral development. Additionally, much moral neuroscience research does not offer clear definitions of morality and often relies on broad or vague descriptions of rule following behavior or situations entailing life and death (see chapters in Zelazo et al., 2010).

Summary and Conclusions

While contemporary approaches draw on the early work of figures such as Freud, Skinner, Piaget, Kohlberg, and Darwin for inspiration in defining the nature and scope of morality, conceptualizations have been broadened and refined to illuminate the complex, multifaceted nature of children's moral development. Socialization approaches continue to focus on processes of internalization and behavioral regulation. However, they have expanded to incorporate both positive and negative affective experiences, highlighting the importance of interactions beyond the discipline context and embracing a more active view of the child. Similarly, structural-developmental theories continue to view judgment and reasoning as the cornerstone of children's moral development while attending to the complex interplay among emotions, cognitions, and behaviors in individuals' evaluations of right and wrong. Additionally, the emergence of evolutionarily based accounts of individuals' predispositions toward care and cooperation, and their underlying neural structures have provided valuable insights into the phylogenetic and ontogenetic roots of morality.

Considered together, research on moral development has shown that from the first years of life, children are concerned with the well-being of others and are motivated toward helping and cooperating with those in their social groups. At the same time, moral development is aided and constructed through children's experiences with family members and peers. The characteristics of the child, their interpersonal relationships with others, and variations in societal and cultural assumptions about the nature of reality all further influence the process of moral development.

Moral Entrepreneur

Abstract

Within the interactionist theory of deviance – or labeling theory – moral entrepreneurs function as rule creators and rule enforcers. Deviance, according to labeling theory, is a result of applying rules to an act, thus moral enterprise constitutes an important part in defining deviance.

The concept of the moral entrepreneur inspired the study of social problems and helped uncover the often professional interests of moral entrepreneurs fighting in an apparently purely ethical battle.

The concept of the moral entrepreneur is an integral part of labeling theory – or rather the interactionist theory of deviance (Becker, 1973) – which sees deviance as the result of the application of rules. In his *Outsiders* first published in 1973 Howard S. Becker argued that deviance is not a quality of the very act itself but is constructed by the reactions of others to the act. By creating and enforcing a rule, others label the agent as deviant and make her/him an 'outsider.' Since values and rules in modern society are far from unambiguous, the act of deciding whether and which rule ought to be applied to a certain practice requires initiative, i.e., moral entrepreneurship. Single persons or social groups act as moral entrepreneurs by establishing their professional and sometimes personal interests as public opinion. They succeed in doing so with the support of additional experts who confirm the gravity of a 'social problem' and use the media and politics to set the agenda, push their views, and enforce the newly created rules.

The Concept

Given the notion that rules have to be created by human beings the question how and when rules are created and enforced has to be answered. Since no social group enforces all its rules without exceptions, the circumstances leading to enforcement are relevant. As Becker explains, an entrepreneur has to take the initiative to punish a culprit, and the group in favor of enforcement of the rule has to gain the attention of others or 'blow the whistle' (Becker, 1973: p. 122). In pluralist societies, competing groups will call for public attention for infringed rules, thus the relative power of a group and its access to the media decides whether it succeeds in alerting the public. Government bureaucracies (e.g., enforcement agencies such as the police) on the one hand and various kinds of experts (e.g., lawyers, psychiatrists, social workers, etc.) on the other hand lend their authority to moral entrepreneurs; however, they themselves have interests that are at times compatible with the original moral entrepreneur who strives to arouse the public. For example, Edwin Sutherland (Sutherland, 1950) shows that psychiatrists had an economic interest in the creation of sexual psychopath laws, which required a psychiatric diagnosis and treatment of the offender. Similarly, each new edition of the Diagnostic and Statistical Manual of the American Psychiatric Association diagnoses more and more mental disorders and thus contributes to 'pathologizing everyday behavior' (Kutchins and Kirk, 1997: p. 21).

The moral entrepreneur appears in the form of the rule creator or moral crusader and in the form of the rule enforcer. The first is interested in the ethical content of the rules, follows a mission by imposing her/his morals onto others in order to better them or 'save' their souls. The moral crusaders are typically middle- or upper middle-class members of society. They are themselves not affected by the vices of those low-life milieus they want to eradicate. Gusfield (Gusfield, 1955, 1967, 1986[1963]) portrayed the members of the temperance movement as paradigm moral crusaders. Similarly, members of the Anti-Pornography Organizations in the USA of the 1960s struggled to defend their values against the permissiveness of liberal culture, which they regarded as threatening by symbolizing a social change that would undermine their social status (Zurcher et al., 1973).

The moral entrepreneur as rule enforcer is far more pragmatic and less purist than the rule creator; after all, the rule enforcer makes his living in prosecuting the deviators from the rule. So, e.g., the police will pride themselves with the successes of prosecution and at the same time report that despite their efforts crime persists or even increases and requires further funding for rule enforcement. As a consequence of the working conditions of the rule enforcers (time and staff constraints, lack of proper equipment, etc.), they will selectively decide when and who to persecute. Becker mentions that an important selection criterion is the suspect's disrespect for the rule enforcer (Becker, 1973: p. 158; Westley, 1953).

According to Becker, enterprise is crucial for deviance, because no initiative of the moral entrepreneur – no rules from which to deviate. And further, without the rule enforcing moral entrepreneur's initiative, infringement of rules would not be detected or persecuted. Becker, therefore, advocated for a shift in the focus of the study of deviance from the rule breakers to the people who make and enforce rules (cf Becker, 1973: p. 153).

Genesis of the Concept: The Quest of American Puritans for a Dry Society

The experience of alcohol prohibition in the USA (the Volstead Act 1920–33) where a reformist social movement succeeded in

establishing its particularistic interest as general moral standard will most probably have furthered questioning the creation and enforcement of rules in general. Consequently, labeling theory provided appropriate answers for intellectuals in a pluralist society such as the USA where Puritans claimed hegemony with the support of government bureaucracies.

David Riesman studying the 'American character' in 1950 mentioned moralizers as key figure of American politics of the nineteenth century (Riesman, 2001[1950]). This self-righteous fervor of moral entrepreneurs of the temperance movement was portrayed by Andrew Sinclair who showed that they would also disdain jazz music ('Does Jazz put the Sin in Syncopation?'), tango dancing, and so on, just as much as tobacco smoking (Sinclair, 1962: p. 181). For Joseph R. Gusfield, the historical case of the American temperance movement stands for a moral crusade, which typically escalates symbolic political controversies so that one group imposes its life style on another (Gusfield, 1986).

So, when Becker created the concept of the moral entrepreneur he could refer to a number of studies about moral entrepreneurs as rule creators intending to better the souls of others by their reformist activities. He himself illustrated the concept with the case of the Marihuana Tax Act and the role the Federal Bureau of Narcotics allegedly played in rounding up legislators for a law prohibiting marihuana (Becker, 1973: pp. 135ff.). A reanalysis of these data by Galliher and Walker (Galliher and Walker, 1976, 1978) challenged Becker's conclusions from this case. However, the concept as such was only questioned by general skepticism toward the allegedly relativistic premise of labeling theory and social constructionist views of deviance.

In 2009, Becker partly revoked his claim that the moral entrepreneurs in the war against opiate drugs, marihuana, and alcohol were by and large motivated by their Puritan views on the vice of seeking pleasure and loss of control with the help of these drugs. In the preface for Dudouet's study of the interests of the pharmaceutical industry fighting the illicit drug trade with the help of government bureaucrats in international organizations (such as the United Nations and its predecessor, the League of Nations), Becker depicts the war on illicit drug traffic as a purely symbolic cover story for controlling the legal market of the raw materials and manufactured narcotics. The influence of the large pharmaceutical companies in the West, both in terms of financial capital on the globalized market and steering political decisions that help in protecting their market positions, is the major power of the moral enterprise of prohibiting drugs, Becker argues (Dudouet, 2009).

Impact of the Concept: The Construction of Social Problems and Moral Panics

Labeling theory influencing many a study of deviance in the 1960s (both in the USA and UK) came under increasing attack in the 1970s. But by the 1980s, the social constructionist approach of moral entrepreneurship experienced a resurrection in the study of social problems. In *Constructing Social Problems* first edited in 1977, Malcolm Spector and John Kitsuse apply the concept of moral entrepreneurship in terms of 'claims-making activities' (2001: pp. 73ff.). While Becker (1966) in a radically social constructivist statement asserts that even nonexistent conditions may make people define social problems (e.g., witches or flying saucers) if they believe in the threat resulting from these conditions, for Spector and Kitsuse the interaction between claims making and responding constitutes the very social problem while defining a putative social condition as a social problem (2001: pp. 75ff.). Evidently, claims making requires the initiative of a moral entrepreneur either as a member of the group affected by the newly defined social problem or as an external evaluator.

The examples of social problem research consequently identify, e.g., various American public health service officials and political decision-makers as driving forces in labeling nicotine smoking as deviant; they were accompanied among others by private enterprises offering quit-smoking-classes who had an economic interest in the campaign (Nuehring and Markle, 1974; Markle and Troyer, 1979). Carolyn Wiener shows how the National Institute on Alcohol Abuse and Alcoholism contributed to the medicalization of alcohol drinking and how this social problem created a vast number of accomplices among the professionals offering treatment for the 'disease' alcoholism (1981). Contrarily, the failing attempts of anticoffee groups to vilify caffeine give an example that despite a health warning of the Federal Food and Drug Administration, the moral enterprise is doomed if its claims are neither supported by (medical) experts nor meet the interests of powerful political and economic allies (Troyer and Markle, 1984).

In the UK, Stanley Cohen (2002[1972]) took up the idea of the moral entrepreneur in his PhD thesis of 1969 where he studied folk devils of the 1960s' youth culture, and how moral entrepreneurs (businessmen, the police, politicians) labeled them as dangerous deviants. Cohen extended the concept with a distinct focus on the public's reaction and created the term 'moral panic,' which is based on the observation that in industrial societies the mass media play an important role in the construction of social problems. Moral entrepreneurs define a social problem and with the help of the media construct a moral panic. Again the economic interests – in this case of tabloid newspapers – constitute a driving force in constructing deviance not the least by the typical claim of the moral panic that the deviant act represents just the tip of the iceberg of some far greater threat to society. Interestingly enough, Cohen remarked in the third edition of his book, that the media themselves are frequently using 'his' term of moral panic, when denouncing a public outcry as hysteria (Cohen, 2002).

In Germany, the concept of moral crusades was applied in studies of the German radical left terrorism of the Red Army Fraction, Rote Armee Fraktion (RAF) of the 1970s (Sack et al., 1984). The German-based Austrian sociologist, Heinz Steinert, concluded that neither the rather small number of terrorist-victims in Germany, nor the nature of the crimes (consisting mainly of bank robberies and not so much political violence in the narrow sense) can account for the media-hype of the terrorist threat. Rather the response of the state to the challenge by the radical left (as it was expressed in various pamphlets and declarations by RAF-activists) denied

any legitimacy to their revolutionary concept and thus assisted their popularity by adding political meaning to 'ordinary' offenses such as bank robberies (Steinert, 1976, 1984: pp. 394ff.). The witch hunt against so-called fellow-travelers ('Sympathisanten') among intellectuals and artists served as a moral crusade in order to establish the border between the friend and enemies of the established order in postwar Germany (Treiber, 1984: pp. 325ff.).

In the 1990s, the study of moral panics was expanded by the historian Philip Jenkins who added analyses of child abuse (Jenkins, 1998), serial murder, Satanism, terrorism, and so on. He underlined that moral panics always serve the interests of occasionally most diverse groups, such as feminists and conservative moralists, law enforcement, child advocates, and professionals in the case of the various cycles of the moral panic on child abuse. In addition, they have to resonate with social needs resulting, e.g., from demographic change.

In 1994, Erich Goode and Nachman Ben-Yehuda offered a systematic theory of moral panics and operationalized the characteristics such as public concern (measured in opinion polls and social movement activities), disproportionality of the concern compared to its 'real' nature (measurable, e.g., in the false perception of a risk that is far less likely than another yet trivialized risk), wide consensus about the concern, volatility, and hostility toward the allegedly deviant group (Goode and Ben-Yehuda, 2009[1994]). They also theorize about the origins of the moral panics and distinguish grassroots panics, panics that are orchestrated by the elite and such carried by the moral or material interests of various interest groups and professionals. While the interest group theory (or assumption) is adequate to summarize a lot of the studies about the construction of social problems, the elitist theory could be suspected to serve as a conspiracy theory about politicians and the media in order to divert attention from the 'real' social problems. An example for the grassroots moral panic is the occasionally exaggerated perception of the danger of radioactivity. With Goode and Ben-Yehuda, the social constructionist tide in understanding the construction of moral panics wanes since their notion of disproportionality claims the existence of objective evidence about the relevance of a concern.

The Concept Today: Moral Entrepreneurs for 'Political Correctness'

As opposed to the term Moral Panic, the term Moral Entrepreneur does not seem to have been incorporated in the public in terms of usage in the popular press as it was studied by Merton and Wolfe (Merton and Wolfe, 1995). Yet, facing any of the present-day outrages about violated norms makes one wonder how the concept of the moral entrepreneur could sink into oblivion. The debate about political correctness from the 1990s onward would lend itself appropriate for an illustration of a moral crusade: the conservatives opposing so-called speech codes (e.g., the National Association of Scholars) warned of imposed orthodoxy in so-called sensitivity trainings and pointed out that the bureaucracies created for particular 'minorities' have an interest in emphasizing differences and promoting complaints in order to justify their very existence.

Further, also liberal advocates of free speech expressed concern about the silencing effect of political correctness and regarded it as a result of identity politics leading to exclusionary practices by moral judgments. Due to the considerable cultural influence of progressives in intellectual circles and academia who at the same time lack political power in society at large, they would tend to use ideology as a bludgeon against each other out of frustration (Aufderheide, 1992).

With new social media the opportunities to enforce pc-codes have multiplied and so have the opportunities for moral entrepreneurs advocating political correctness.

Abstract

Students of deviance, social problems, and politics have used the concept of a moral panic to describe sudden concern over a group or activity, accompanied by calls for control and suppression. Out of an infinite range of potential perceived threats, one – which may or may not be new – is suddenly the center of considerable attention. The news media, public officials, religious leaders, and private 'moral entrepreneurs' are key in focusing public attention on the issue, typically by identifying some recognizable group as 'folk devils' responsible for the menace. Human history has been full of rumors, fears, and efforts – often deadly – to constrain or eliminate the human source of perceived problems.

Students of deviance, social problems, and politics have used the concept of a moral panic to describe sudden concern over a group or activity, accompanied by calls for control and suppression. Out of an infinite range of potential perceived threats, one – which may be neither new nor on the rise – suddenly receives considerable attention. Marijuana use, motorbikes, and rock 'n' roll music are common examples. The news media, public officials, religious leaders, and private 'moral entrepreneurs' are key in focusing public attention on the issue, typically by identifying some recognizable group as 'folk devils' – usually young people, racial and ethnic minorities, or other relatively powerless groups – responsible for the menace. New political or legal policies are sometimes the result, and new symbols and sensibilities (available as the raw materials for future panics) almost always are.

The Concept of Moral Panics

Trying to understand a 1964 incident in which massive police and media attention were given to an evening of rowdy behavior by young people at an English seaside resort, British sociologist Stanley Cohen first formulated the concept of a moral panic in 1972, borrowing the term from his colleague Jock Young. In Cohen's (1972) words,

> A condition, episode, person or group of persons emerges to become defined as a threat to societal values and interests; its nature is presented in a stylized and stereotypical fashion by the mass media; the moral barricades are manned by editors, bishops, politicians and other right thinking people; socially accredited experts pronounce their diagnoses and solutions; ways of coping are evolved or (more often) resorted to; the condition then disappears, submerges or deteriorates and becomes more visible.

The key idea, attractive to cultural constructionists, is that the public reactions and rhetoric are not clearly linked to any objective measure of threat. Scholars who use the concept of moral panic frequently try to show that the rates of the activity are actually declining or at least not increasing, or that those promoting the panic have interests in doing so that are independent of the actual harm done (for instance, police departments may receive more funding if they can persuade the public that Satanic child abuse is rampant). The term 'panic' seems to imply a disproportionate or self-defeating response, although the feelings and thoughts of those panicking will probably be the same regardless of the extent of any real threat. Although some involved in a panic are cynically trying to manipulate public opinion, others (presumably those being manipulated) really do perceive the putative threat as real.

Most scholars have examined panics over aspects of lifestyle considered – at least by those embracing them, but also usually by the analyst too – to be harmless personal choices, such as clothing styles, sexual choices, or substance use. For them it is easy to show that, under certain value systems, any repressive action is unwarranted. Others have applied the term to actions that are clearly harmful, such as child abuse, but in which the response appears exaggerated or misplaced. For them it is more difficult to show that the response is disproportionate, although they may show that it is ineffective. The term has also been used to describe those opposed to technologies such as nuclear reactors. It is assumed that the emotional dynamics of a panic are similar in these diverse cases.

Many observers have found the concept of moral panics useful because it opens a window onto a society's disagreements over basic values, often intuitively felt ones, as well as onto fears and anxieties that are normally submerged. A panic over child abuse may reveal broader concerns over changes in family structure; one over water fluoridation, fears of government bureaucracy; one over crack cocaine, racist attitudes toward African American urban youths. Cultural meanings rarely reveal themselves so starkly.

Moral Panics in History

Human history has been full of rumors, fears, and efforts – often deadly – to constrain or eliminate human sources of perceived problems. When the Black Death came to Europe in the fourteenth century, neither physicians nor priests were of much help, so large numbers of frightened Germans blamed the Jews who lived among them, exterminating most and driving the rest into Central and Eastern Europe. Because few disasters have been as widespread as the plague, few panics have been as broad, but local instances have been common throughout known history.

In the nineteenth century more systematic efforts appeared, especially in the UK and the USA, to make the lower classes conform to the expectations of the middle and upper classes, especially those aspects of lifestyle considered (by those behind the efforts) to be part of moral character. Drinking, cruelty to animals, neglect of children, pornography, even movies came eventually to be seen as antisocial behaviors that well-intended benevolent societies tried to extirpate, partly for the good of the lower classes themselves. Unionization, rebellion, and urban riots too were seen as little more than a form of crime or bestiality. For more than 100 years, most moral panics consisted of the privileged worried about the less privileged. (Although lower-class panics persisted, such as anti-Catholic riots in the USA.)

For most of this era, intellectuals were more likely to contribute to moral panics than to analyze, and thereby criticize, the panics of others. Few scholars questioned the widespread fears of urban mobs that characterized the middle and upper classes of nineteenth-century Europe. In fact, they contributed to them, especially by dismissing 'crowd' behavior as irrational.

There seems to have been some kind of turning point around World War II, since which the sources of moral panics have grown more diverse. Intellectuals and academics, as they grew in numbers in the 1950s, instigated something like mild panics over conformity, the authoritarian personality, and mass society as signs of vulnerability to fascism or communism. Politicians were behind many of the panics over communist infiltration. Grassroots issue entrepreneurs seem to have motivated the American panic over fluoridation, however. In the USA, the majority of moral panics since the 1970s have been the work of the religious right, whose diligent organizing is one reason the USA seems to have more panics than most other advanced industrial nations. There, panics frequently cluster around sex for pleasure rather than procreation (loose morals, homosexuality, teenage pregnancy, abortion), around race and poverty (crack and other drugs, welfare mothers, urban crime and violence), and around immigration (the English language, standards in the schools, overpopulation, job and wage competition). Each panic carries with it clearly defined folk devils.

Although moral panics are hardly new, they seem to have become more frequent in recent decades, or at least more visible to national audiences. For one thing, advanced industrial societies have a 'social movement sector' of professional activists who act as moral entrepreneurs as they try to attract attention, funds, and volunteers. Such individuals have long existed – think of Thomas Paine or Anthony Comstock – but they now have extensive formal organizations, political networks, and direct-mail fund-raising techniques at their disposal. Second, immigration into many countries has increased in recent decades, accompanied by heightened tensions over group boundaries, especially ethnic ones. Newcomers often have habits that are poorly understood and easily used to stigmatize the group. Increased penetration of the media, especially television, into each and every 'deviant' subculture has further spread awareness of alternative life-styles, especially sexual freedoms. The Protestant right in the USA and elsewhere has discovered the power of life-style panics for raising funds, if not recruiting new members.

The Role of the Media

Much of the 'panic' in moral panics – the disproportionate nature of the response – is due to framing and amplification by communications media. If they do not report on a phenomenon, or do not frame it as something one should be frightened about, there is rarely a panic. Thus the rise of television everywhere and the wide readership for tabloid newspapers in the UK, for example, have been blamed for an increase in moral panics. In some views, the media reflect the values and interests of economic and political elites, and so focus on the groups and behaviors that frighten these elites. In a less conspiratorial view, the media simply look for unusual life-styles and behaviors as a means to attract viewers, readers, and so on. In doing so, they spread information about what mainstream culture considers deviant. Sometimes, it is deviant enough to ignite panic.

Cohen (1972) originally described three ways in which media coverage contributes to moral panics: in the exaggeration and distortion of what actually has happened; in predictions that the same kind of thing will happen again; and in the framing of key symbols in pejorative ways. To a large extent, these make the event or behavior into news.

Variations in Panics

A number of variations in culture and social structure affect the shape and outcomes of moral panics. One of the most important is the political, and especially the electoral, system. Where, as in the USA, politicians are left to raise their own funds and do their own campaigning in single-district elections, they may be tempted to play on the fears of the majority, which often have to do with life-styles of minorities. Where, as in Sweden, representation is more proportional and political parties control the chances of individual candidates, party leaders at least have the opportunity to curb efforts at creating moral panics for electoral purposes. Of course, this allows entire parties to play the panic card, as in the case of the National Front in France.

The structure of the media industry also has an effect. In some nations governments exert considerable control over the content of the media – although the widespread relaxation of such control in recent years may have contributed to an increase in moral panics. Their intervention allows governments to curb sensationalism and prevent moral panics, but it also allows them to incite them to their own advantage. On another dimension, in countries with nationally centralized news media, such as the UK, panics can spread more quickly than in countries where the media are more regional and local, as in France or the USA.

Other potential moral entrepreneurs face varying kinds of incentive structures. Local police departments, for instance, may need to appeal to city or regional governments for additional funding. Certain occupations may have opportunities for advancing into new terrain because of moral panics. The more that a taxation or funding system allows input from local units or from the general population, the more tempting it is for those whose funding comes from these sources to use moral panics to increase their budgets.

Some moral panics reflect widespread public anxieties and fears that are easily stirred up through news coverage. Others seem traceable to specific interest groups who will benefit from the panic. Goode and Ben-Yehuda (1994) distinguish three models of moral panics, according to their origin. In one view, moral panics are relatively grassroots in origin, in a second they are organized by elites, and in a third vision they are promoted by interest groups or social-movement organizations. But there is no reason to think that all panics must come from the same source, so that one model would fit them all. Goode and Ben-Yehuda's typology functions equally well for distinguishing different types of panic as different scholarly models: some panics are indeed more grassroots in origin, others are more elite-directed, and yet others are promoted initially by social-movement groups. In addition, some seem entirely a creation of the news media. These types may differ in their dynamics and outcomes as well as their origins.

As for differences in the general public, many commentators have assumed (more than demonstrated) that there are national differences in susceptibility to 'mass mobilization' in instances such as moral panics. It has been thought that a lively 'civic culture' should prevent the kind of demagoguery often associated with moral panics, and that formal education breeds tolerance for the alternative life-styles that are often demonized in panics. This evidence is not as strong as one might wish. Just the kind of educated, normally tolerant people one might expect to resist moral panics often end up leading them. One of their frequent (if not defining) features is the relative absence of critical, dissenting voices.

Controversies

The concept of moral panics has not lacked critics. Like all varieties of cultural constructionism, the analysis of moral panics can be turned against those who use it. Just as they find bias and exaggeration in their subjects of study, so their own critics can claim to find the same flaws in research on moral panics. Most scholars who have used the concept have been left-leaning and thus quicker to discern panics on the right, for instance. A more fundamental criticism is that the term panic is necessarily pejorative, assuming rather than demonstrating that those analyzed are not entirely rational. To prove irrationality or disproportionality, analysts must presumably investigate the goals of those accused of panic (often a complex and poorly defined cluster of goals) and show that they are undermining their own progress toward those goals.

Debates over the utility of moral panics as an analytic tool tap into deep disagreements about the rationality of protest and politics. For most of the modern era, students of collective protest viewed it as immature, irrational, or manipulated, a kind of crowd dynamic leading people to do things they would not do otherwise. In this tradition panics, like fads, were analyzed in the same way as movements for unions or civil rights. To critics, moral panics are a holdover from this pejorative vision that dismissed protestors as irrational.

In recent decades a very different view of such activity has arisen, in which collective action is seen as a pervasive and regular form of politics, in which groups and individuals organize to pursue their own interests. They mobilize resources, look for political opportunities in which to act, and formulate rhetoric to appeal to as many potential supporters as possible. The concept of panic seems to undermine this positive view of such activity, but in fact it focuses attention on precisely the dynamics that this rationalist perspective tends to overlook. Issues must be chosen from a myriad of possibilities; grievances must be constructed; emotions must be aroused, often through the demonization of others; previously private issues must be portrayed as a public concern. The dynamics highlighted by research on moral panics, in other words, characterize a great deal of politics both institutionalized and not.

Moral panics remain a common occurrence in modern societies. They generate considerable scholarly interest, although some care must be taken to avoid loaded language and tendentious arguments about them – and some will always think that the term 'panic' itself is necessarily loaded.

Moral Reasoning in Psychology

Elliot Turiel, Graduate School of Education, University of California, Berkeley, CA, USA

Abstract

Developmental research has focused on reasoning about right and wrong in social relationships. Piaget and Kohlberg each proposed sequences in which children first develop moral judgments that are confused with nonmoral features, such as adherence to social conventions, and then judgments differentiating them from each other. However, subsequent research shows that young children form concepts in the moral domain with understandings of welfare and fairness, differing from judgments about social conventions. Moral decisions entail coordination of different concerns – moral and nonmoral – in situational contexts. Individuals critically apply moral judgments to cultural practices entailing social inequalities.

Moral reasoning, involving concerns with welfare, justice, and rights, has been analyzed extensively by philosophers. Informed by philosophical expositions, psychologists have researched the development of moral judgments from early childhood to adulthood. A large body of research has revealed that young children begin to develop distinct judgments about avoiding harm to others and promoting welfare, along with other domains of social reasoning. Development in the moral domain also involves increased understandings of justice and rights. In concrete social decisions and actions there is a coordination of different domains of thought including morality, the conventions of social systems, and areas of personal jurisdiction. Since many social systems are hierarchically organized, conflicts can be generated by the application of moral judgments to existing inequalities and injustices.

The term morality has been used in different ways, and its explanation is subject to a great deal of debate. One controversy pertains to whether morality is particular to cultures or if aspects of morality are applicable to humans across cultures. These debates also include considerations as to whether moral values are arbitrarily set in a group, society, or culture or are absolute in that they must be categorically followed. However, the most useful conceptualizations on either side of these debates pertain not to arbitrary values *or* absolutism, but to morality that forms part of integrated cultural systems, which might differ from culture to culture *or* moral precepts that are in general applicable across situations but which are not absolute in that they might not be applicable in all situations. Various explanations have been provided as to how individuals acquire the morality of their culture, including ones that emphasize the learning of a set of values or the incorporation of cohesive systems of moral thought (*see* Moral Development, Cultural Differences In). Some maintain that moral judgments are based on intuitions that do not involve reasoning. However, an alternative psychological perspective, with roots in philosophy (e.g., Immanuel Kant, John Stuart Mill, John Rawls, Martha Nussbaum) is that morality involves reasoning about right and wrong with regard to social relationships, legal systems, and societies.

Social Interactions and Moral Judgments

In psychology, much research has focused on the development of moral reasoning, involving constructions of judgments about how social relationships ought to occur, with understandings of welfare (avoiding harm and promoting good), justice (in the distribution of goods, and equal worth of persons), and rights (group and individual). Such understandings are a function of children's social interactions and emotions seen to occur the world over.

Two developmental psychologists have had a deep and lasting influence on thinking about moral development. One is Jean Piaget, who is regarded as one of the foremost contributors to developmental psychology more generally. Piaget's (1932) research on children's moral judgments was conducted in the late 1920s when sociologically oriented views of morality were predominant in the social sciences. As an example, the sociologist Emile Durkheim (1925/1961) had proposed that morality constitutes a shared respect for the rules and values of society, and that children must be educated to form a strong emotional attachment to the group and to respect its rules and authority. Piaget, by contrast, examined the ways children construct ideas about rules, authority, fairness, and equalities. The influence of Piaget's theory of moral development on psychology was limited until the early 1960s. Up to that point, greater attention was given to psychoanalytic and behavioristic theories, each of which explained moral development as the incorporation of society's standards. The research of Lawrence Kohlberg (1969) served to refocus attention on moral reasoning.

Two Moralities and Two Types of Social Interactions

Piaget examined the organization of children's thinking and how they interpret events. In his work on moral development, he observed children's use of rules in playing games, sharing (distributive justice), punishment (retributive justice), and intentions or consequences in assessing responsibility for transgressions. He proposed a sequence of two broad levels of children's moral judgments connected to two ways they relate to others. In the first, children (approximately 4–7 years) are

heteronomous in their moral thinking and have unilateral respect for adults in authority. Heteronomy is characterized by absolutistic judgments, whereby social rules are regarded as fixed and requiring strict adherence. As an example, young children reify game rules, judging that they cannot be altered even if all the participants were to agree to the changes. They also believe that adults' commands must be followed to the letter. Children also judge actions by their material consequences rather than by the actor's intentions.

In part, heteronomous thinking is due to inherent relationships of inequality. Young children attend mainly to the greater power and status of adults – which imbues adults with moral authority. In later childhood there is a shift in moral thinking that occurs with increasing interactions with peers, which provide children with more opportunities to experience mutuality, reciprocity, and cooperation. As a consequence children shift from heteronomy to autonomy, defined as involving participation in the elaboration of norms (as opposed to receiving them readymade). Through the reciprocity in relationships of equality children construct understandings of justice and mutual respect, which they differentiate from obedience to authority and strict adherence to rules.

Stages in the Development of Moral Judgments

In extensions of Piaget's research, further emphasis was placed on the need to ground social and behavioral research on definitions of the realm. In the dominant approaches of the time, considerations of the psychological means by which children acquire morality were addressed without formulations of the substantive elements of morality. Kohlberg (1969), especially, was instrumental in combining psychological with philosophical analyses (relying to a fair extent on neo-Kantian philosophers such as Rawls, 1971). One reason for stressing inclusion of philosophical formulations was that Kohlberg proposed that children think systematically about moral matters, forming organized ways of thinking about concepts of justice, rights, and welfare.

Kohlberg, too, regarded the development of moral judgments to involve progressive differentiations or distinctions in moral and nonmoral understandings. In his research, children were presented with hypothetical stories that depicted conflicts around issues of life, physical well-being, trust, law, authority, and retribution. (A well-known story depicts the conflict of a man who must decide whether to steal an otherwise unavailable drug to save his wife's life.) Kohlberg formulated a sequence of stages and levels that portrayed children's moral judgments somewhat differently from Piaget's characterizations. In particular, it appeared that young children do not reify rules nor possess an unyielding respect for authority (according to Kohlberg, Piaget had misinterpreted a moral orientation to power and sanctions as reification). Rather, in the first two stages (labeled a 'preconventional' level) moral judgments are not differentiated from material value, sanctions, power, and attaining people's needs and desires. In early adolescence, there is a shift to thinking about morality primarily in terms of social expectations and maintaining the social order by upholding laws and authority (the 'conventional' level). After attaining understandings of morality as rooted in rules or laws and the need to maintain the social order, there emerges a way of thinking that includes applying moral judgments to society and its practices, rules, and authority. At the most advanced level (the 'postconventional'), which does not develop at least until late adolescence, concepts of justice, fair treatment, rights, and respect for persons are differentiated from the existing social order. At the most advanced level, individuals make moral judgments about society's system of laws and norms.

Distinguishing Morality from Other Domains of Social Judgment

During the latter part of the twentieth century Piaget and Kohlberg influenced a great deal of research. However, the patterns of developmental changes they described have been questioned. In particular, research indicates that young children's moral judgments are neither heteronomous nor based on a confusion of moral value with material value or sanctions. One line of research demonstrates that young children have positive orientations to matters like helping and sharing (*see* Prosocial Behavior and Empathy). Another line of research shows that young children develop understandings of welfare and fairness distinct from understandings of other social domains (Turiel, 2006). Using research methods that do not pose complex conflicts between moral and social considerations (as was the case in Kohlberg's methods), it was demonstrated that children do not treat all rules as fixed, do not solely have unilateral respect for authority, and do not judge by sanctions.

Children's moral ideas stem from interactions with children and adults that involve observing and experiencing harmful consequences, inequalities, or violations of freedoms. These moral judgments differ from another set of judgments about social uniformities that can be termed 'conventions.' Conventions are socially expected behaviors that coordinate interactions within social systems. Such uniformities in behavior gain their force from being customary and allow for greater efficiency in that people know what to expect of each other. Children do not judge moral issues (such as hitting or stealing) by the existence of uniformities, agreements, rules, or common practices. For instance, rules pertaining to moral issues are judged not to be legitimately alterable by general agreement or dependent on what authorities dictate, or relative to the social and cultural context. Maintaining the welfare and rights of persons, as well as promoting fairness in social interactions and cultural practices, guides evaluations of actions, rules, authorities, and the organization of social systems.

By contrast, conventions, such as those pertaining to modes of greeting, forms of address, or dress codes, are judged by children to be alterable by consensus, contingent on common use, rules, or authority expectations, and relative to social contexts. Thus, children judge violations of conventions to be wrong only insofar as there is a governing rule or if it is dictated by an authority (e.g., a conventional rule in a school can be changed by the principal). Similarly, conventions are not generalized across contexts in that it is judged that other cultures can legitimately have a different set of customary behaviors.

Morality is a fundamental domain of social reasoning. Children's judgments within the moral domain, which begin to emerge at a fairly young age, do not entail reification of rules or confusion with other social domains. Changes in moral reasoning occur with age. A young child's moral reasoning is focused primarily on welfare – preventing harm and promoting welfare. Older children and adolescents develop increased understandings of justice and reciprocity among persons, which they coordinate with concepts of welfare. Research has also shown that young children's moral judgments are associated with the early emergence of emotions like sympathy, empathy, and affection. It appears that such positive emotions are more important to the development of morality than negative emotions like shame, guilt, and disgust. Moreover, children's actions are connected with the types of moral judgments they make. It has been demonstrated that the moral judgments of children and adolescents about hypothetical situations closely correspond to their judgments about actual events they experience (Turiel, 2008).

Coordination in Moral Decision-Making

The different domains of social reasoning have implications for explanations of how people make decisions in social situations. Decision-making involves coordination in that the different domains, as well as different considerations within the moral domain, are taken into account and priorities are drawn. These processes of coordination have been examined in research on honesty or trust, and on rights. For example, whereas honesty is generally considered morally right, in some circumstances it is not necessarily the morally correct course of action. An example discussed in philosophical discourse is a situation in which lying might be necessary to save a life. Studies with adolescents and adults show that they consider it acceptable to deceive a person who directs someone to engage in acts considered morally wrong. Similarly, coordination of different considerations is seen in decisions about rights like freedom of speech and religion. Although children and adults endorse rights, in many situations they subordinate rights to matters like preventing harm or promoting community interests.

Social Hierarchy and Social Justice

People make social decisions by which moral judgments are applied in concrete situations and in the context of societal arrangements. Social hierarchy, by which groups are accorded greater or lesser power is an important feature relevant to moral, social, and personal activities considered out of the boundaries of conventional or moral regulation. Often, hierarchical distinctions are made on the basis of social class and gender (Nussbaum, 1999).

Since women are often in subordinate positions in the social hierarchy, they experience injustices and inequalities, and in some cases are victims of oppression. The social system, therefore, can further the personal interests of some (e.g., males) at the expense of others (e.g., females) through social expectations and practices. Such arrangements constitute a source of tension and conflict within social systems. Whereas people in lower positions are part of the social system and do accept norms and practices, at the same time they are critical of aspects of social arrangements. In many respects, moral reasoning produces social harmony since people are concerned with the welfare of others and promoting fairness. Another side of morality, however, is that it can result in conflicts and efforts at subverting societal arrangements judged to be counter to welfare, justice, and rights. Research in several patriarchal cultures has shown that females judge cultural practices entailing social inequalities to be unfair and attempt to achieve changes toward greater justice (Abu-Lughod, 1993; Turiel, 2002).

Morality 'East' and 'West': Cultural Concerns

Kwang-Kuo Hwang, National Taiwan University, Taipei, Taiwan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

'Eastern' moral systems entail the ethics of community or the ethics of divinity, which emphasizes the importance of fulfilling one's duties or attaining to group goals. In contrast, 'Western' morality highlights an individual's right of choice with utilitarian consideration, rather than any enforced social demand of deontological concern. Negative duties are universal moral codes in most human societies, while positive duties are specific to non-Western societies, which are experiencing transformation in order to preserve their core values under the impact of Western individualism.

Comparison of Three Methodologies

Three main approaches in the social and behavioral sciences inform the comparative study of moral reasoning and behavior prominent in 'Western' societies following the Judeo–Christian tradition and 'Eastern' societies following Confucianism, Islam, and Hinduism: developmental psychology, anthropological ethnography, and cultural psychology. These three approaches result in different understandings of morality in the 'West' and the 'East.' This article first offers a comparison of the methodologies of these three approaches and then provides a detailed examination of research on Western and Eastern moral systems.

Developmental Psychology

Kohlberg's (1981) theory of moral development and research methods were widely adopted by child psychologists in the 1970s and 1980s to study the cognitive development of moral reasoning and moral judgment in children of varying ages in different cultures. Based on the assumption of cross-cultural universality in moral development, Kohlberg claimed that "All individuals in all cultures use the same basic moral categories, concepts, and principles, and all individuals in all cultures go through the same order on sequence of gross stage development, though they vary in rate and terminal point of development" (Kohlberg, 1971: p. 175). His theory consists of six universal stages of cognitive development in moral judgment.

Kohlberg's theory adopts the perspective of evolutionism, which is based on a normative model and classifies a great diversity of moral discourse from a multitude of cultures into several categories arranged in a formal sequence. According to his theory, the development of moral reasoning follows a universal invariant sequence toward the goal of thinking with universal ethical principles.

A series of empirical studies have been conducted using Kohlberg's standardized moral dilemmas and scoring manuals (Marchand-Jodoin and Samson, 1982; Parikh, 1980). After careful examination of the literature, Snarey (1985) found that because stage skipping and stage regressions were rare, progress from Stage 1 to Stage 3 or 4 was virtually universal, but that the presence of Stage 4/5 or 5 was extremely rare in all populations. Nearly all samples from Western middle-class groups and 91% of Eastern urban populations exhibited some Stage 6 principled reasoning. No tribal or folk cultural groups of the non-Western world showed any postconventional thinking. Postconventional thinking upholds individual rights or universal ethical principles.

Many of the moral reasoning data collected in collectivist or communalistic societies of the non-Western world either could not be scored according to the standardized manual or could not be explained in the context of Kohlberg's theory (e.g., Maqsud, 1979; Sullivan, 1977; White et al., 1978). Such anomalistic facts have been used to challenge Kohlberg's theory. Critics charge that though Kohlberg's preconventional and conventional stages are well based on empirical operative judgments, his descriptions of higher stage reasoning at postconventional stages are primarily based upon Kant, Rawls, and other Western philosophers (Snarey, 1985). This perspective entails Western ideologies of rationalism, individualism, and liberalism, and therefore assigns the values of male, Caucasian, American intellectuals as the end point of moral maturation (Buck-Morss, 1975; Edwards, 1985). The theory's ethical objectivism ignores the moral discourse prevailing in many non-Western societies, and fails to recognize their substantial ethical philosophies (Weinreich-Haste and Locke, 1983). Imposing Kohlberg's theory as well as his scoring system on the moral reasoning of non-Western peoples may result in systematic bias originating from Western ethnocentrism.

Gibbs (1979) tried to revise Kohlberg's theory in terms of Piaget's phylogenetic perspective. According to Piaget, human intelligence is a holistic phenomenon encompassing social, moral, and logico-physical aspects. Its development follows a standard sequence that is predetermined by epigenetic factors like those of other species. Along with completion of physical maturation and the singular achievement of intellectual development over the course of the adolescent years, there is a progressive ability for people at the highest stage of standard development to reflect on the very conditions of their existence in the world. Reflection on one's own existence may motivate one to define a moral theory to justify one's basic moral principles from a particular standpoint that is either inside or outside the society (e.g., Stacey, 2011).

As many studies have shown, different cultures show wide variety in their philosophies of morality. These normative philosophies may provide material for second-order thinking or metaethical reflection when individuals try to define their

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64005-9

own moral theories. It is impossible for individuals to eliminate cultural influences from the contents of their own moral reasoning. Considering this fact, a better way to conduct cross-cultural research on morality would be to use ethnographic analysis to describe the patterns of moral conduct and moral thinking that consistently emerge in the daily social life of people in a particular culture.

Anthropological Ethnography

Researchers who study the ethnography of morality usually adopt the viewpoint of interpretive anthropology, which assumes that culture is an organized collection of symbols with the major function of maintaining social order for normal operation (Erickson and Donald, 1997; Gubrium and Holstein, 1997). As derivatives of the cosmology of a given culture, the concepts of morality and personhood, as well as other symbolic systems, can best be understood in the holistic context of that culture.

Many anthropologists have used the ethnographic approach to study indigenous religions, cosmology, personhood, and concepts of morality in non-Western societies (e.g., Edel and Edel, 1959; Howell, 1997). They tend to adopt the insiders' point of view to interpret the moral ideas, moral discourse, and moral practices in a particular society. Instead of relying solely on philosophical analysis and anthropological records, they pay special attention to the dynamic interplay between abstract moral principles and particular social events in a given community.

Researchers following this approach have often adopted the viewpoint of relativism for depicting the uniqueness of each culture. Paradoxically, members of a cultural community tend to insist on the viewpoint of absolutism: They may believe that their moral standard is superior to that of other cultural groups, and use it as a criterion for defining what is meant by *person* or for differentiating their own group from outsiders (Hcelas and Lock, 1981; Carrithers et al., 1985; Rapport, 1997). Those who violate their moral standards might be condemned as *not a person*. The process of dehumanization may lead to severe interpersonal or even intergroup conflict in extreme cases (e.g., Melhuus, 1997).

Cultural Psychology

Cultural psychologists investigate the cultural foundation of psychological diversity in self-organization, cognitive process, emotional function, and moral reasoning among people living in different cultures. In order to understand native peoples' symbolic and behavioral inheritance in terms of their shared framework of interpretation, cultural psychologists also adopt an ethnographic approach, but with the perspective of pluralism. Pluralism assumes that people all over the world are similar in their psychological structure and function, although aspects of their knowledge, thinking, feeling, values, needs, and behavior are activated by the experience of living in a particular cultural community. Cultural psychologists advocate the slogan: "One mind, many mentalities; universalism without uniformity" (Shweder et al., 1998: p. 871). They work to develop universal theoretical frameworks for interpreting the thinking and behavior of people in different cultures. Although it would be impossible to depict all moral systems in the world, it is possible to describe the sharp contrasts between moral systems of the East and West with the conceptual schemes provided by cultural psychologists.

Morality

Cultural psychologists suggest that three main domains of moral discourse exist in human society: the ethics of autonomy, the ethics of community, and the ethics of divinity (Shweder et al., 1997). Because the moral experiences of human beings are so complicated and the recognition of reality so restricted, even though all moral systems contain elements of all three of these domains, any particular moral system will tend to emphasize a particular domain of moral discourse.

Morality of the West

The contemporary Western moral system is characterized by the ethics of autonomy, which can be traced to the Judeo–Christian religious tradition. Christianity assumes that the world was created by God, who also created humankind in accordance with His own image. Since all humans were created in God's image, all humans are equal. Every person has the essence of humanity and should obey the divine commandments declared by God.

This concept of person and its underlying discourse of divinity changed drastically after the Renaissance in Europe. The Cartesian philosophy of dualism detached individuals from the outer world where they find themselves. Rationalism emphasized an individual's free will and subjective reasoning. The expansion of modern capitalism also made significant contributions to the rise of individualism (Turner, 1988).

The Western concept of self-formed, in the cultural milieu of individualism, requires a dualistic view of the world. It draws sharp distinctions between mind and matter, cognition and affection, self and society, nature and culture, and so on. Self is conceptualized as "a dynamic center of awareness, emotion, judgment and action organized into a distinctive whole and set contrastively both against other such wholes and against its social and natural background" (Geertz, 1974: p. 225). The inner life of the self, with its spontaneity, privacy, uniqueness, genuine feeling, and constancy, has a clear-cut boundary that separates it from the outer social world constituted by mask, role, rule, or context.

In the Western view of personhood, the individual is conceived of as prior to and more fundamental than society, which is treated as an artificial construction designed mainly to satisfy human needs. When a social order can no longer serve the function of realizing this end, it should be redesigned and reconstructed to restore its function. Based on this premise, Western morality is characterized by an emphasis on the rights of individuals. According to Dworkin (1977), all moral codes encompass personal rights, personal duties, and social goals, but they may differ in the priority given to these three categories. Western morality is premised on the concept of natural rights, rather than on natural duties or social goals.

Because individuals are construed as quasi-sacred and absolute, their legitimate demands should be carefully respected.

The individual is an ultimate and indivisible monad, and every human group is made up of monads with the same human nature. Individuals' free will and right to liberty are natural, fundamental, and inescapable. By the same token, the duty to respect others' rights is equally natural and inescapable. One's rights are restrained by the identical rights of other individuals, and everybody is encouraged to strive for the rights of all human beings to the greatest overall liberty (Dumont, 1986).

The realization of negative duties of omission (e.g., not killing, not cheating, not stealing, etc.) is considered to be the prerequisite of a moral agent. Violating moral codes of this category might be condemned as evil. In contrast, the practice of the positive duties of commission is subject to an individual's right of choice. Individuals who decide to undertake an altruistic act may be admired for their virtue. As a consequence, a certain state of tension is frequently aroused between social demand and the individual's desire for freedom of choice. The autonomous view of self tends to entail the belief that performing social obligations in spite of individual rights may have the negative effect of restricting one's own personal liberties. Even if one can justify working for the benefit of another person, the act of undertaking this responsibility is a resolution of personal choice with either utilitarian or contractrian consideration, rather than an enforced social demand of deontological concern.

As indicated by Gilligan (1982), in contrast to the Kohlbergian ethics of justice for males, the moral reasoning of Western females can be characterized by the ethics of caring and responsibility. However, both the deontological view of morality held by Kohlberg and the morality-of-caring framework developed by Gilligan are bound to the Western culture of individualism. Both stress freedom of choice and individual responsibility. Commitments to interpersonal caring are viewed as matters of personal decision (Miller, 1994), rather than as obligations to a particular social target in Eastern societies (Mohmood, 2005).

Morality in the East

In sharp contrast to the individual-centered morality of the West, contents of moral systems in the Eastern world, no matter whether they originated from Confucianism, Hindusim, Islam, or Buddhism, can be described as duty based. Unlike typical Western dualism, most Eastern philosophies advocate a monistic view of origin. That is, one's life is construed as an inseparable part of the world in which one finds oneself, not as an independent entity standing in opposition to the outer world. For example, traditional Chinese philosophy conceives of the formation of all things in the universe as the result of dynamics between the two opposing forces of *ying* and *yang*. A person's life is also produced from the unification of *ying* (female) and *yang* (male). In Confucianism, a family is conceived of as the body of a human being; each role in the family represents a distinct part of the body. For instance, the relationship between parent and child is like that between flesh and bone, while brothers are considered to be the four limbs (Hwang, 1999).

The Hindu view of life is also premised on the functional interrelatedness of the universe. From the earliest times of *Rigveda* (about 1500 BC), the Hindus believed that *Rta* (dynamic equilibrium) is the governing dynamic principle underlying functional equilibrium of the cosmic order. The famous *Purusha sukta of Rigveda* assumes the functional relatedness of all living organisms. Any existing phenomena many attain a state of *Rta* when each of its parts remains in its proper place and functions in its own law of activity. Humans, animals, and plants are interrelated. They all are part of the cosmic immanent life force. The individual functioning of one in coordination with the individual functions of others results in collaborative equilibrium of the whole universe (Heimann, 1964). In the same vein, Hindus conceptualize their society as a huge cosmic organism in which certain functions are allotted to each of the four major parts: the head, arms, trunk, and feet. Each of these four represents one of the four castes of Hindu society. Remaining in the proper function fulfills the goal of smooth collaboration of the whole society.

Instead of drawing the boundary of an individual around the immediate surface of one's physical body, most Oriental philosophies conceive of this boundary as expandable to include one's family or the whole society. Followers of Oriental philosophy tend to believe that external forces predetermine the social order. Role relationships within one's primary group are especially unchangeable through one's own efforts. Therefore, Oriental moral systems endow mandatory features not only to negative duties of omission, but also to some positive duties of commission. Examples include filial piety (unconditional positive duty) and loyalty (conditional positive duty) in Chinese society (Hwang, 1999, 2012), repaying *on* (favors or kindness) in Japanese society, and *utang na loob* (debt inside oneself or a debt of gratitude) in Filipino society. These kinds of positive duties or categorical imperatives urge individuals to fulfill obligations to specific targets in the community. These obligations ensure the smooth functioning of society, rather than protect the rights of individuals. In Dworkin's (1977) conceptual framework, Eastern moralities are based on duties or group goals rather than rights (Ahmed, 1993; Ali, 2006).

Compared with Western ethics of autonomy, ideas about individual rights are relatively uncommon in traditional Eastern moralities. Even moral discourse arguing for negative duties in Eastern moral systems are proposed not on the premise of protecting individual rights, but in consideration of maintaining social order or for religious reasons. For example, the act of killing others violates the principle of benevolence (*ren*). *Ren*, the requirement that all people carry out their moral duty to significant others in their intimate society, is the most fundamental moral rule for maintaining psychosocial homeostasis in Chinese society. Buddhists must adhere to five requirements: do not kill, steal, lie, be lustful, or taste intoxicants or meat. Violation of any of these requirements may result in *Karma* bringing automatic retribution in a later life. According to Islam, the present life is short and temporary, while the future life is eternal and everlasting. Those who devote themselves to charity, especially those who sacrifice themselves for the almighty Allah, may ascend to Heaven. Those who indulge in evil doings will descend to Hell. This kind of moral discourse fits within the model of Eastern moral systems that entail the ethics of community or the ethics of divinity, rather than the ethics of autonomy.

Moral discourse supporting the ethics of community or divinity in the Oriental world as revealed by sages or prophets

are recorded in classics such as *The Analects* of Confucianism, or religious scriptures such as the Qur'an of the Muslim faith, or the *Upanishads* of Hinduism. Intellectuals who are able to interpret those classics or scriptures, like Confucian scholars in traditional China, Brahmans in Hindu society, priests in Islamic countries, and monks in Buddhist societies, have occupied high positions in traditional and even contemporary societies. Their position is similar to that of priests in the Christian world before the European religious Reformation movement.

In contrast, the modern Western view of morality advocates a position of secularism, which assumes that all moral agents morally equivalent. Anyone can discover the natural law of morality without the assistance of revelations by a prophet or sage.

Global Ethics and Cultural Change

Since the collapse of the Soviet Union and East European communist regimes at the end of the 1980s, most countries have been incorporated into the world economic system of capitalism. The rapid expansion of opportunity for intercultural contact and exchange between people from the East and West has facilitated the formation of such concepts as multiculturalism and global ethics in the age of globalization. As part of the Universal Ethics Project sponsored by UNESCO, a group of international scholars of philosophy have proposed a Universal Declaration of Human Responsibilities, consisting of a list of global ethics with four categorical imperatives proposed on the basis of a fundamental demand that every human being must be treated humanely (Kung and Kuschel, 1993):

> You shall not kill!
>
> You shall not steal!
>
> You shall not lie!
>
> You shall not commit sexual immorality!

An examination of the list reveals that it consists of negative duties found in most cultures, while positive duties specific to a particular Eastern culture are undergoing drastic cultural changes under the impact of Western individualism, commercialism, and materialism. For example, as an unconditioned positive duty in Confucian culture, filial piety has been the core value of familism in East Asian societies. Empirical study on the basis of a dual model distinguishing between reciprocal and authoritarian filial piety indicated that diverse evolutional paths of contemporary filial piety do appear in such Chinese societies as Taiwan, Hong Kong, and China, with a general tendency of diminishing importance in authoritarian filial piety, while reciprocal filial piety remains its persistence (Yeh et al., 2013). In accompany with such cultural changes, the traditional pattern of arranged marriage has evolved several transitional patterns of mate selection in East Asian countries, but autonomous marriage has become the shared trend with cohort variation in Japan, Korea, and Taiwan (Tsutsui, 2013). By the same token, intergenerational relations in those areas share similar features in both of its change and continuity patterns: while coresidence between generations remains patriarchal, the main flow of integer support is from adult children to parents. Sons tend to perform various filial duties much more than daughters, but the actual practice of filial responsibility tends to be shared among adult siblings according to their various resources instead of by the birth order of sons (Lin and Yi, 2013).

Abstract

This article looks at the origins of human morality, and examines the contributions of both biological evolution and cultural evolution. Biological evolution may help explain certain categories of moral behavior (such as altruism), as well as certain morally relevant capacities (such as empathy). Cultural evolution may explain how different moral systems emerge in different times and places, and why they tend to foster aspects of human nature that enhance group success and discourage aspects of human nature that undermine it. Morality must be understood as the joint production of both biological and cultural evolution.

> The ant, the bird, the marmot… have read neither Kant nor the fathers of the Church nor even Moses. The idea of good and evil has thus nothing to do with religion or a mystic conscience. It is a natural need of animal races. And when founders of religions, philosophers, and moralists tell us of divine or metaphysical entities, they are only recasting what each ant, each sparrow practices in its little society.
>
> —Peter Kropotkin (1898), *Anarchist Morality*.

Morality Is a Mess

This might seem like a strange place to begin a discussion of the origins of morality, but let me explain why I think it's a useful starting point. Scientists strive for simple, parsimonious explanations for phenomena. Those that meet this standard are described approvingly as *elegant* explanations. It seems unlikely, however, that morality will ever have an elegant explanation, for the simple reason that morality is not an elegant phenomenon. Like many human institutions, it is a messy aggregation of a vast array of competing influences. These influences include inclinations rooted in the biology of human nature, such as a tendency to favor kin, a tendency to resent freeloaders, and a capacity to empathize with the suffering of others. They also include influences that can be classified broadly as cultural. Among these are norms designed to rein in socially disruptive aspects of human nature, norms aimed at furthering the interests of the individuals or groups promoting them, and – at least occasionally – genuine efforts to work out the logical consequences of universal principles of justice and the common good. If we focus on any of these influences to the exclusion of the others, we will arrive at a lopsided view of the nature of morality – hence the importance of keeping in mind that morality is a mess.

In this article, I consider both the biological and cultural evolution of our formal moral systems. I begin with the evolution of altruistic behavior, which is the area of moral behavior that evolutionary theory has shed the most light on. I then consider some of the putative evolved mechanisms underlying human morality, such as inhibitions against harming innocents, the capacity for empathy, and an aversion to incestuous mating. Finally, I consider the cultural evolution of morality and why some moral systems thrive and persist whereas others fade away.

The Problem of Altruism

In 2011, the Australian state of Queensland suffered extreme flooding. As with any disaster, this one left many tales of heroism in its wake. Among the most poignant is the story of 13-year-old Jordan Rice. Jordan had been shopping with his mother and his younger brother, Blake. As they drove home, they were caught in a flash flood. They ended up on the roof of their car, stranded precariously in the middle of raging waters. Eventually, help arrived. A local man tied a rope to himself and made his way to the car to try to rescue the family. Jordan insisted that the rescuer save his little brother first. Before the rescuer could return, Jordan and his mother were swept away and drowned.

By putting his brother ahead of himself, Jordan lost his life. This act of selflessness represents the height of moral action. But from a simplistic Darwinian perspective, it is puzzling. At first glance, evolutionary theory seems to imply that the organisms that survive and leave behind the most descendents will be those that look after number one. That's exactly what Jordan Rice didn't do. How could natural selection have spared a tendency for such self-sacrificial behavior? Of course, we might wonder whether natural selection is relevant to the question; perhaps Jordan was simply brought up in a culture that prizes self-sacrifice. But that is probably not the whole story, because comparable acts can be found in other animals. For instance, birds in some species feign injury to lure predators away from their babies in the nest, only attempting a getaway at the very last minute. Likewise, bees sting invaders to the nest, protecting the colony but losing their lives in the process. Self-sacrificial altruism is surprisingly common in nature. What might be going on?

Kin Selection

Over the past half-century, evolutionary biologists have made great strides in answering this question (Alexander, 1987; de Waal, 2006; Krebs, 2011). The single-most important theory of animal altruism – and the one most relevant to the examples given above – is William Hamilton's (1964) *kin selection theory* (*see* Kin Selection; Kinship, Evolution of). According to standard neo-Darwinian theory, a gene can be selected if it has effects that boost its replication rate relative to rival versions of the same gene (Dawkins, 1976). This can happen in a number of circumstances. Most obviously, it can happen if the gene increases its bearer's chances of surviving and reproducing. But it can also happen if the gene increases *another* organism's chances of surviving and reproducing, as

long as the other organism is more likely than chance to possess the same gene. Close relatives are more likely than chance to possess any given gene, and thus a tendency to help close relatives can potentially be selected. This process is called *kin selection*. Kin selection is the explanation for feigned injury in birds: The heroic bird's babies in the nest are more likely than chance to carry any genes contributing to the development of injury feigning. Kin selection is also the explanation for the suicidal nest defense of bees and other eusocial insects: Their close kin in the nest are more likely than chance to carry any genes contributing to the nest defense tendency. And kin selection may be an important part of the explanation for Jordan's sacrifice: His brother was more likely than chance to possess genes contributing to whatever motivations and inclinations underpinned his selfless behavior. Of course, shared genes were the last thing on Jordan's mind; he was merely acting on his inclinations. But kin selection is plausibly part of the explanation for how those inclinations evolved in the first place. Needless to say, the relationship between kin selection and morality is far from simple. After all, moral systems tend to oppose certain forms of kin altruism: those we label 'nepotism.' Nonetheless, kin selection helps to explain a class of behavior that we typically view as moral: altruism among kin.

Reciprocal Altruism

Hamilton's theory explains most of the altruistic behavior seen in other animals. However, it does not explain most of the altruistic behavior seen in human beings, because much of this involves nonrelatives. Certainly, the kind of extreme altruism exemplified by Jordan Rice may be more common among kin than nonkin. But more common, less costly forms of altruism in our species often take place between unrelated people (Stewart-Williams, 2007). Nonkin altruism is hard for the evolutionist to explain, but there are various possibilities. The best known is Robert Trivers' (1971) *reciprocal altruism theory* (*see* Sociobiology: Overview). This starts from the fact that individuals working together can often produce more than the sum total of what each could produce working alone. If five hunters working together bring down one giraffe, for example, they end up with more meat per hunter than if each working alone brings down one turtle. Thus, cooperation is better for all involved. Reciprocal altruism utilizes this principle but smears the cooperation out across time: I help you when I can; you help me when you can. This sounds like a good arrangement, so why don't all animals do it? The main stumbling block is *the problem of cheating*. Although it is better to trade favors than to act selfishly, it is better still to reap the benefits of someone else's help but then not return the favor. Because cheating pays more than mutual helping, mutual helping is evolutionarily unstable. It is displaced easily by a tendency to exploit helpers. The only way that mutual helping could evolve is if it coevolves with psychological 'machinery' that somehow defends against cheats. According to Trivers, many of our standard-issue emotional responses do exactly this. People unconsciously keep track of favors given and received, and when a trading partner (e.g., a friend or ally) starts taking advantage, people naturally respond with anger and moral indignation. This motivates them to punish the cheat or to cut off further aid, which protects them from exploitation. These and other psychological dispositions can be viewed as an evolved moral psychology (see also Cosmides and Tooby, 1992).

Trivers' theory has been tested in various ways. Most notably, it has been explored *in silico* – that is, using computer simulations (Axelrod, 1984; Axelrod and Hamilton, 1981; Nowak and Sigmund, 1992). In a typical simulation, virtual organisms encounter one another repeatedly and must either cooperate or defect (i.e., cheat). Points are awarded based on how well they do in each encounter. The virtual organisms are programed with various strategies, from very simple ones (such as Always Cooperate or Always Defect) to very complex, conditional ones. Among the most successful strategies, and by far the most famous, is Tit-for-Tat. Tit-for-Tat works like this. The first time it encounters a new player, it cooperates. In every subsequent encounter, it simply does whatever the other player did the last time they met. If the other player cooperated, Tit-for-Tat cooperates, thereby continuing a mutually beneficial cooperative partnership. If the other player defected, Tit-for-Tat defects, thereby cutting off the option of further exploitation. Tit-for-Tat is not always the most successful strategy; it all depends on who it's up against. But the general picture emerging from this research is that strategies *like* Tit-for-Tat – strategies that cooperate conditionally but defend against cheats – tend to do better than overly nice or overly nasty strategies.

Reciprocal altruism appears to be relatively rare among nonhuman animals, although there is evidence for it in vervet monkeys (Seyfarth and Cheney, 1984) and vampire bats (Wilkinson, 1984), among others. In contrast, many lines of evidence suggest that reciprocal altruism is an important part of the explanation for nonkin altruism among humans (see, e.g., Delton et al., 2011; Gurven et al., 2000; Hames, 1987).

Sexual Selection

Reciprocal altruism is not the only contender, however. A more recent attempt to explain our altruistic streak is based on an older theory: sexual selection theory (Darwin, 1871). Sexual selection is a form of natural selection. It occurs when a trait is selected, not because it enhances its bearer's survival prospects, but because it increases its bearer's *reproductive* prospects – that is, its ability to attract mates or outcompete same-sex rivals for mates. According to sexual selection theory, the mate choices of one sex can give rise to elaborate sexual ornamentation in the other. The enormous nose of the male proboscis monkey is a striking example. Females prefer to mate with males with larger-than-average noses. This preference, acting over many generations, gives rise to the male's impressive proboscis. In humans, not only the females but the males as well possess 'ornaments' that the other sex finds attractive (Stewart-Williams and Thomas, 2013). This includes secondary sexual characteristics such as women's hour-glass shape and breasts, and men's V-shaped torso and deep voice (Barber, 1995). According to some evolutionary psychologists, sexual selection has also produced behavioral ornaments, and among these are altruism and morality (Miller, 2007; Zahavi, 1975). These traits are costly, hard-to-fake displays of fitness, designed by selection to attract mates (*see* Human Mate Choice, Evolution of). Geoffrey Miller has made

the strongest case for altruism and morality as sexually selected ornamentation. The following quote is from his book *The Mating Mind*:

> Murder, unkindness, rape, rudeness, failure to help the injured, fraud, racism, war crime, driving on the wrong side of the road, failing to leave a tip in a restaurant, and cheating at sports. What do they have in common? A moral philosopher might say they are all examples of immoral behavior. But they are also things we would not normally brag about on a first date. (Miller, 2000: p. 292)

Several lines of evidence support the sexual selection theory of altruism. First, just as female proboscis monkeys prefer males with enormous noses, men and women tend to prefer mates who display kindness and generosity (Buss, 1989). Second, men are particularly likely to provide help in circumstances where doing so might demonstrate their fitness and enhance their mating prospects. So, for example, men are more likely than women to help when helping is dangerous and an audience is present, especially when the recipient of the help is a woman (Eagly and Crowley, 1986; Johnson, 1996). In a similar vein, Hawkes (1991) has made a strong case that big-game hunting is at least partly a matter of men showing off to obtain mates. The spoils of the hunt are not channeled preferentially to kin or used to pay off earlier debts; instead, the meat is shared widely throughout the group. What explains this altruistic sharing? According to Hawkes, the best hunters tend to have higher status and more wives and more affairs than other men – a finding that fits well with the sexual selection hypothesis. Certainly, sexual selection could not be the whole explanation for human altruism. It does not apply to altruism among kin, for instance, as kin are not potential mates (except in rare and unfortunate cases). But there is enough evidence now to think that sexual selection may be one piece of the puzzle.

Group Selection

The final theory of altruism we'll consider is also the most controversial. This is the idea that altruism is not a product of selection among individuals, but rather of selection among groups. The concept of group selection traces back to Darwin (1871) who, in *The Descent of Man*, suggested that groups of altruists would fare better than groups of selfish individuals, and thus that altruism would slowly displace selfishness. The subject was brought to center stage nearly a century later, when V.C. Wynne-Edwards (1962) argued that organisms in many species had evolved to sacrifice themselves for the good of the group. The main impact of Wynne-Edwards' work was to inspire a strong counterargument. Critics like G.C. Williams (1966) pointed out that any organisms that sacrificed themselves for the group would quickly be displaced by those that sat back and let others make the sacrifice while they pumped out as many offspring as possible. Although the critics conceded that group selection was possible in principle, most concluded that it was unlikely in practice. During the 1960s and 1970s, the idea that adaptations evolve for the good of the group was largely expunged from evolutionary biology, and replaced with the idea that adaptations evolve for the good of individuals and their kin (Dawkins, 1976; Williams, 1966). After several decades in the wilderness, however, a more sophisticated form of group selection is now gaining attention (Nowak, 2006; Sober and Wilson, 1998; Wilson, 2012). Modern group selectionists do not claim that group selection is the only selective force, and thus the approach is probably better named *multilevel selection theory*. Advocates of this theory (e.g., Wilson and Sober, 1994) distinguish between within-group selection and between-group selection. Within-group selection favors traits that advantage the individual, but between-group selection favors traits that advantage the group. Organisms, it is claimed, are the net outcome of these countervailing forces. When there are small differences in reproductive success within groups, but big differences in average reproductive success between groups, selection is concentrated at the level of the group. According to the multilevel selectionists, this is precisely what has happened in our species. As such, we have an evolved tendency to extend help not only to relatives but to nonrelatives in our group, even when they cannot reciprocate, and even when there is no scope for sexual or reputational benefits (a phenomenon known as *strong reciprocity*; Gintis, 2000).

Although group selection is currently enjoying a new lease of life, so too are criticisms of the theory. Some critics charge that group selectionists are too willing to attribute any instance of human sociality and cooperation to group selection (Pinker, 2012). Humans are certainly prosocial animals, but prosociality is not necessarily selected for the good of the group. As the theories described above show, it can be selected instead for the good of prosocial individuals and their kin. And there are several reasons to favor individual-level selection over group-level selection as the explanation. First, the individual-level approach has been much more empirically fertile than group selection. Second, in many ways, humans do not look like we're strongly group selected (Pinker, 2012; Price, 2012). Parents spend many thousands of dollars each year on their children, but if they also give several hundred dollars to charity, this is considered uncommonly altruistic (Singer, 1981). Grandparents routinely look after their grandchildren without payment; nonrelated group members generally do not. People happily share with family and friends, but they have to be cajoled and coerced to pay their taxes. If humans were strongly group selected, why would we need tax collectors? Why would we need conscription? Why would we need ethical codes that admonish us to prioritize the interests of the group? Certainly, extreme altruism among nonrelatives is hard to explain in terms of individual-level benefits – consider, for instance, the soldier who throws himself on a grenade to save the rest of the group. But such acts are rare, and it is usually a mistake to invoke natural selection to explain rare acts. Of course, group selectionists have responses to all of these criticisms, and the issue remains as yet unresolved. But with persuasive arguments on both sides, the group selection debate is currently one of the most exciting debates within evolutionary behavioral science (*see* Human Cooperation, Evolution of).

A Mind Made for Morality

Until recently, altruism was the main area in which Darwinian theory has been used to explore moral psychology. But altruism

is only one component of morality, and over the past decade or so, evolution-minded thinkers have begun exploring others. In the process, they have started to shed light on some of the psychological mechanisms underpinning moral behavior. So, for instance, according to Jonathon Haidt's *Moral Foundations Theory* (Haidt and Joseph, 2004), the human mind comes factory equipped with a set of moral tastes, including a desire to reduce the suffering of others, a sense of fairness, loyalty to the in-group, emotions and attitudes guiding behavior toward people of lower versus higher status, and a desire for purity and the avoidance of contamination. Other thinkers have focused on moral emotions, such as guilt, shame, contempt, anger, disgust, compassion, and sympathy (de Waal, 1996; DeScioli and Kurzban, 2009; Rozin et al., 1999). In this section, I discuss four putative psychological mechanisms underpinning human morality – namely, inhibitions about harming other people, the capacity for empathy, a sense of fairness, and an aversion to incest.

Trolleyology

Arguably, the most famous contemporary research in moral psychology is based on a hypothetical moral dilemma imported from philosophical ethics. The dilemma – which has been described as the white lab rat or the fruit fly of moral psychology – involves an out-of-control trolley (i.e., train) careening down the track and heading toward five workers on the line. You are standing there watching, and you realize that if the trolley continues on its present path, it will kill the five workers. In one version of the dilemma, you just so happen to be standing next to a lever. If you pull the lever, it will divert the trolley to another line, saving the five. Unfortunately, there is one person on the other line, and that person will be killed instead. What do you do? If you're like most people, you divert the trolley, killing one person but saving five (Hauser et al., 2007). But now imagine a second scenario. You are standing on a footbridge over a railway track, watching the trolley hurtle toward the five workers. This time you cannot divert it. Standing next to you, however, is a fat man (or, if you prefer, a man with a heavy backpack). Somehow you calculate that, if you push the man onto the track, his weight will be sufficient to stop the trolley in its tracks before it kills the five – but the man will die in the process. You are not heavy enough to stop the trolley, so you cannot make the ultimate Wynn-Edwardsian sacrifice and throw yourself on the track instead. What would you do in this situation? If you're like most people, you would *not* push the man (Hauser et al., 2007). But from a utilitarian perspective (according to which the right action is the one that produces the greatest good for all involved), the two dilemmas are morally identical: Either one person dies or five die. Why do we respond so differently?

Joshua Greene and colleagues (2004) have argued that people have a built-in aversion to directly and intentionally harming innocent people, and that, as a result, they are willing to pull the lever but not push the man. It is a matter of debate whether such an aversion is a product of natural selection as opposed to learning or culture. But the fact that the pattern is so widespread across cultures has led many to the former view. Interestingly, although people's decisions do not differ a great deal across cultures, their *explanations* for them do (Hauser et al., 2007). This suggests that, to some extent, moral training simply furnishes us with rationalizations for an unreasoned aversion that we would possess anyway (see Haidt, 2001).

Empathy

Closely related to this is the capacity for empathy. Empathy involves understanding what others are experiencing and having the appropriate emotional responses to it – for example, sympathizing with others' suffering (Baron-Cohen, 2011). Although culture and experience may amplify or diminish our empathetic tendencies, there are several reasons to suppose that the basic capacity for empathy is a product of natural selection. For one thing, the first flowerings of empathy appear very early in the life span (Warneken and Tomasello, 2009). As Paul Bloom has observed, toddlers often become upset if a nearby adult is upset, and they may even offer up a teddy bear or favorite blanket to make the adult feel better. In addition, some nonhuman animals may be capable of empathy. The strongest case has been made for large, intelligent animals like chimpanzees and dogs (de Waal, 1996). However, some researchers have argued that even mammals as diminutive as rats have some rudimentary capacity for empathy (Bartal et al., 2011). Patricia Churchland (2011) suggests that empathy originally evolved to allow mammalian mothers to attend to the needs of their offspring. In some lineages, however, natural selection later co-opted the neural mechanisms underpinning maternal empathy and applied them to other social relationships, including relationships with mates, unrelated allies, and ingroup members.

Although empathy is an important ingredient for morality, by itself it is not sufficient for morality. Indeed, as various commentators have pointed out, empathy can sometimes be morally misleading (e.g., Bloom, 2013). We easily empathize with our friends and neighbors' smallest hurts but may fail to empathize with the millions of people starving in the developing world. Thus, doing the right thing sometimes involves going against the advice of our empathy and listening instead to the voice of reason. But although empathy is not sufficient for morality, it is hard to imagine that someone who lacked empathy entirely could be truly moral (Prinz, 2005). Empathy is an important building block of human morality, and one that plausibly has its origin in our evolutionary history.

A Fairness Instinct?

A more contentious claim is that human beings have a built-in sense of fairness – a 'fairness instinct,' as David Barash put it. The most common way of exploring this issue is a decision task known as the Ultimatum Game. The game involves two players: the Proposer and the Responder. The Proposer is given a sum of money – say, $10. Her task is to propose how that money should be split between herself and the Responder. The Proposer could suggest a 50–50 split, or a 90–10 split, or any other combination. Then it's the Responder's turn. The Responder has only two options: accept the proposal or reject it. If he accepts it, they both get the proposed sums of money. If he rejects it, no one gets anything. In a world where people were perfectly rational and entirely self-interested, Proposers would

elect to keep $9 and give away only $1, and Responders would accept any nonzero offer – why opt for nothing when you could have $1? But that is not what usually happens. In Western nations, Proposers usually offer $4–5, and Responders usually reject anything less than $3. The Proposers are not acting irrationally; they know that if they make a lowball offer, the Responder will resent it and reject it, so they make an offer the Responder will accept. The Responders, in contrast, *are* acting irrationally, because their insistence on punishing unfair offers leaves them out of pocket. That, at any rate, is the verdict of classical economics. But closer inspection suggests how this tendency could be adaptive. For most of our evolutionary history, humans rarely encountered people they would never encounter again. A willingness to respond angrily to unfairness – in this case, to reject a stingy offer even at some personal cost – signals to the world that you are not the sort of person who will accept mistreatment. Although this may be self-destructive in the short term, it may be beneficial in the longer term, as it means that people will think twice about mistreating you next time around.

Thus, the Ultimatum Game findings have been used as evidence for an evolved distaste for unfairness. The problem is, though, that the results described so far come exclusively from Western nations. When Joseph Henrich and colleagues (2005) took the Ultimatum Game to 15 small-scale societies, they found that people in these societies behaved very differently than Westerners. Among the Machiguenga horticulturalists of Peru, for instance, Proposers often made low offers – and Responders often accepted them. Even more surprising, among the Au and Gnau of Papua New Guinea, Proposers often made *high* offers – offers of up to 70% of the pot – and Responders turned them down! Henrich concluded that the alleged fairness instinct is actually a set of cultural norms: norms that grow up in cultures that are embedded in a market economy and in which people must cooperate closely to eke out a living.

The issue is further complicated by the fact that other researchers have found evidence for an incipient sense of fairness in nonhuman animals. Brosnan and de Waal (2003) trained capuchin monkeys to exchange pebbles for food. Sometimes the capuchins received pieces of cucumbers for their pebbles; sometimes they received grapes. The monkeys preferred the grapes, but they were quite happy to receive the cucumber – as long as their neighbor was only getting cucumber, too. However, if the neighbor started getting grapes, while they continued to get cucumber, the capuchins threw a tantrum. Indeed, they often threw the cucumber away forcefully. The monkeys were not perturbed by inequality per se. Some collected more stones than others and therefore earned more treats, but onlookers did not throw tantrums about that. Instead, they were upset that another individual got a better reward for the same behavior. In other words, they didn't want an equal distribution of wealth; they wanted equal pay for equal work. The capuchin sense of fairness is a far cry from our own. For one thing, capuchins only object to unfairness when they are on the receiving end of it (although see Brosnan et al., 2010). Nonetheless, the fact that these less culture-bound creatures possess anything like a sense of fairness makes it harder to believe that our own sense of fairness is purely a cultural invention. Although it is not yet clear how to reconcile the capuchin findings with the cross-cultural Ultimatum Game findings, the solution may relate to the fact that the term 'fairness' is being used in subtly different ways in the different studies. In the Ultimatum Game, it means equality (i.e., a 50–50 split); in the capuchin research, it means equity (i.e., equal pay for equal work). It may be that, rather than having an evolved aversion to deviations from a 50–50 split, humans have an evolved aversion to unfairness or mistreatment more generally, with some flexibility in what exactly this means from culture to culture (*see* Human Cooperation, Evolution of).

Incest Aversion

There may also be biological contributions to some aspects of our sexual morality. The best example concerns incest. In many species, our own included, inbreeding is highly detrimental to fitness. The offspring of incestuous liaisons often do not survive, and when they do, they have an elevated risk of genetic abnormalities. It is plausible to suppose, then, that we possess psychological adaptations that tend to steer us away from incestuous mating. Given the strong evolutionary rationale for such adaptations, it is probably no coincidence that most people feel acute disgust at the idea of sex with siblings or other family members. A powerful case has been made that humans have an evolved tendency to develop a sexual aversion to individuals they grow up with, especially during the first five or so years of life (Fessler and Navarrete, 2004; Lieberman et al., 2007). This negative sexual imprinting is known as the *Westermarck effect* (Westermarck, 1921; Wolf, 1995). Now it might be argued that incest aversion is a cultural invention: Perhaps earlier peoples observed that incestuous mating led to birth defects and the like, and therefore proscribed it. But this does not fit the facts. Societies have proscribed many forms of sexuality over the ages: adultery, premarital sex, and so on. Sometimes the proscription works; sometimes it does not. But when it does, it is usually because people manage to resist temptation, not because they're disgusted by the act in question. In contrast, most people are profoundly disgusted by the idea of incestuous mating, and they feel this way despite receiving little socialization against incest: Parents generally worry about their teenagers having sex with nonrelatives, not with siblings. It is plausible to suppose, then, that an aversion to incest is a product of natural selection. The moral precept 'Incest is wrong' is presumably *not* a direct product of natural selection. However, it may be an idea that we readily accept, given the nature of human nature (*see* Incest Prohibition, Origin and Evolution of).

The Cultural Evolution of Morality

This brings us to the topic of the cultural evolution of morality. Although some suggest that morality is a product of biological evolution – an adaptation like eyes and wings – there are several reasons to view it instead as the joint product of both biological and cultural evolution (Mesoudi and Danielson, 2008; Stewart-Williams, 2010). First, moral codes vary tremendously across cultures and times (Prinz, 2005). In modern Western societies, most people deem cannibalism, slavery, and torture to be self-evidently wrong; in earlier times, however, and across a wide range of cultures, they were

deemed morally permissible. Similarly, during the twentieth century, the West underwent a profound shift in modal attitudes to such issues as homosexuality, premarital sex, and the treatment of ethnic minorities. Certainly, there are still differences of opinion within Western culture: People disagree bitterly about the morality of abortion, capital punishment, casual sex, drug use, and euthanasia. But this too is difficult to square with the notion that morality is a direct product of biological evolution (although see DeScioli and Kurzban, 2009). A second reason to look beyond biology is the fact that morality often goes against the grain of our raw biological impulses. For instance, the principle that we should 'turn the other cheek' goes against the natural impulse to harm those who harm us. If turning the other cheek were biologically adaptive for our ancestors, we would presumably possess an evolved appetite for it. This is not to deny that, at least in some cases, morality simply reflects our natural inclinations; think, for instance, of our nepotistic streak and our aversion to incest. But often morality looks more like a set of cultural norms designed to put the brakes on socially divisive inclinations. A final reason to doubt that morality is a biological adaptation in any simple sense is the fact that we strive to teach our children to be moral. Although young children spontaneously help others in a way that even adult chimpanzees do not, parents and teachers still spend a lot of time encouraging children to share and not to hurt their playmates. They might not create children's prosocial tendencies out of nothing, but they clearly try to amplify them. Once again, this suggests that the norms and ideals we bunch together under the heading 'morality' must be understood as the joint production of both biology and culture.

In this final section, I examine three theories about how moral systems might evolve culturally: (1) the memetic approach, according to which moral ideas come to predominate in a group to the extent that they are good at replicating themselves; (2) cultural group selection, according to which moral ideas come to predominate in a group to the extent that they promote the group's interests; and (3) gene-culture coevolution, according to which cultural changes in moral ideas (or indeed any aspect of culture) can alter biological selection pressures and lead to downstream genetic change.

Moral Memes

The first approach to cultural evolution is the memetics approach. Richard Dawkins (1976) coined the term 'meme' to refer to a unit of culture: an idea, a word, a ritual, a tune. He then argued that, just as natural selection among genes favors genes that are good at replicating themselves, so too natural selection among memes favors memes that are good at replicating themselves. A central insight of the theory is that the memes that come to predominate in a culture are not necessarily those that are good for us. They *may* sometimes be good for us, but that's not the reason they are selected. Memes are selected because they are good for the memes themselves, where goodness is defined in terms of their ability to spread from mind to mind and to persist in a culture. Applied to morality, the claim would be that moral memes are selected not because they enhance reproductive fitness, or because they benefit individuals or groups, but instead because they are good at selfishly replicating themselves. The memetic approach does not necessarily conflict with the earlier material. Indeed, the earlier material may shed light on why some moral memes succeed whereas others fall out of the meme pool. Memes must adapt to relatively fixed aspects of human nature. So, for instance, a moral system that prohibited any form of nepotism – including the tendency to feed and clothe one's own offspring rather than the next-door neighbor's offspring – would be unlikely to persist in the meme pool, as it would clash too violently with our evolved kinship psychology. Moral memes must also adapt to the current cultural setting. The fairness meme, for instance, seems to prosper better in market economies than in small-scale societies.

The memetic perspective may help explain some otherwise-puzzling features of morality. Consider, for instance, the first four of the Hebrew 10 Commandments: have no Gods before me; make no graven images; do not take God's name in vain; and keep the Sabbath holy. These have nothing to do with harm avoidance, or justice, or any other major moral principle. At a push, it could be argued that they foster social cohesion. But the memes'-eye view raises an alternative and often-overlooked possibility: These commandments help to protect the religious system that they are a part of. They may be viewed as part of a large cluster of memes – a memeplex – 'designed' by memetic selection to perpetuate itself. Critics of memetics note that, thus far, the approach has yielded little in the way of empirical findings. Nonetheless, it is an appealing approach, which alerts us to the possibility that at least some moral memes may exist not because they help us, but simply because they help themselves.

Cultural Group Selection

A second approach to cultural evolution goes by the name of *cultural group selection*. This is selection for the good of the group, but at the level of cultural elements rather than genes. Richerson and Boyd (2004) argue that group selection at the genetic level was probably weak in our ancestral past, as there was too much gene flow between groups. There was much less 'meme flow,' however. Even today, neighboring forager tribes are often genetically indistinguishable, but speak mutually unintelligible languages. If this kind of asymmetry was typical throughout our evolutionary history, there would have been much greater scope for cultural group selection than for genetic group selection. The sociologist Emile Durkheim long ago suggested that institutions such as morality function as social glue, binding together large-scale societies. Cultural group selection provides a possible mechanism for bringing about such institutions.

Many aspects of morality are potentially explicable in terms of cultural group selection. One example is the Western institution of monogamy. The most common mating pattern in ancestral societies was a mixture of monogamous and polygynous marriage (Marlowe, 2003). As Henrich and colleagues (2012) note, though, several centuries ago, European cultures established a norm of monogamous marriage. This norm applies even to high-status men who, in traditional societies, would often have taken several wives. The monogamy norm cannot be explained as a direct product of natural selection; after all, it is historically recent and, to some extent, pushes

against our evolved tendencies. How, then, did it come about? Henrich et al. suggest that groups that instituted monogamous norms had a number of advantages over those that did not. For a start, crime rates and rates of violence are generally lower in monogamous than polygynous societies. This is because polygynous societies are overrun with bachelors – if one man has four wives, three men must have none – and when young men have no wives or mating opportunities, they are more likely to cause problems (Daly and Wilson, 2001). In contrast, groups adhering to the monogamy norm have fewer such problems. These groups were therefore more productive and wealthier. They grew faster and persisted for longer. Furthermore, other groups, observing their success, may have copied them. In this way, the monogamy meme spread – despite the fact that it clashed to some degree with human nature (*see* Marriage Systems, Evolution of).

Cultural group selection is probably not a complete explanation for morality. As the philosopher David Hume (1777/1999) pointed out, certain virtues – those he called the "monkish" virtues: celibacy, fasting, penance, and the like – are not useful for society in any obvious way. But cultural group selection does help to explain a deep trend in our moral systems: the fact that they generally encourage aspects of human nature that facilitate social harmony, and discourage aspects of human nature that upset it.

Gene-Culture Coevolution

The final approach – gene-culture coevolutionary theory – is distinguished by its emphasis on the interactions between biological evolution and cultural evolution (Cavalli-Sforza and Feldman, 1981; Durham, 1991; Lumsden and Wilson, 1981) (*see* Gene-Culture Coevolution). The classic example of gene-culture coevolution concerns the capacity to digest lactose in milk even after the age of weaning. This is found almost exclusively in populations with a long history of dairying. One might suppose that the capacity to digest lactose came first and that the cultural practice (dairying) followed. It seems, however, that it was the other way around: Dairying came first and established a selection pressure that led to the evolution of life-long lactose digestion (Laland et al., 2010). A similar process may have shaped human morality. Richerson and Boyd (2004) suggest that gene-culture coevolution helps explain why humans are so much more altruistic and prosocial than other animals (see also Boehm, 2012). In their view, our hypertrophied altruism stems originally from cultural group selection (*see* Human Cooperation, Evolution of). Groups that established and enforced altruistic norms did better than other groups, lasting longer and growing more rapidly. Once the prosocial norms were in place, though, people whose genes fitted them to this social milieu prospered and had more offspring. In time, the relevant genes crowded out competing variants. Thus, biological evolution reinforced the cultural tendency and amplified our altruistic dispositions.

Conclusion

Morality is a complex phenomenon that resists any simple explanation. It is the net outcome of a tangle of conflicting causal influences. These include both biological and cultural influences. Biology affects morality in various ways. First, some forms of moral behavior, in particular altruism, have their origin in our evolutionary history. Second, formal moral systems sometimes reflect aspects of human nature. This includes, for example, the proscription on incest among biological relatives. Third, certain evolved capacities provide the basic building blocks for morality. This includes the capacity for empathy and emotions like anger, disgust, and guilt. And fourth, biology may constrain our moral systems: Moral systems that conflict too violently with human nature may be unlikely to persist.

In addition to these biological influences, cultural evolution may help to explain the moral systems that crop up in different places and times. Ultimately, moral memes must possess properties that enable them to stick around in the culture. In many cases, the property in question may be the fact that they enable groups holding those moral memes to prosper and persist. Finally, not only does biology shape morality but morality may shape biology. It may do this by setting up selection pressures that, over many generations, fit people to the demands of the local moral system.

This article is a revision of the previous edition article by A. Spencer, volume 15, pp. 10047–10053, © 2001, Elsevier Ltd.

Abstract

Morphology, the study of the correspondences between grammatical information, meaning, and form inside words, is one of the central linguistic disciplines. In this short presentation we briefly review the units it identifies, the processes used to build new words and alter the grammatical properties of existing words, and some of the main underlying theoretical questions currently under debate: (1) whether morphology is independent from syntax; (2) what is the nature of the basic units of morphological analysis; (3) the division of labor between lexical listing and word formation; and (4) how idiosyncratic information that plays a role in word grammar is distributed across different linguistic components.

What Is Morphology?

Morphology is the area of linguistics that studies the grammatical information contained in WORDS, and the one that explores how words are related to each other according to their shared meaning and form. Take, as an example, the Spanish word in (1), where the accent marks the phonological position of stress, not the actual orthographic convention.

(1) Cantarémos
'we will sing'

For a morphologist, what is relevant about (1) is that it is a verb (whose infinitive is *cantar*, 'to sing'), specifically a first person plural form (that is, corresponding to *we*), in a particular tense (future) and a particular mood (indicative): something that the traditional grammars have called a simple future form. Linking these pieces of information to the form of the word can be done in various ways (see the section 'Morphemes or Words?' for details). One of them is to see if it is possible to correlate distinct pieces of information with segments inside the word. By comparing (1) to other forms of the same verb, some morphologists would conclude that:

1. *-mos* is associated with the information 'first person plural,' as *-mos* in (1) occupies a position that other segments fill when the verbs appear in other persons and numbers: e.g., *cantaré-mos* versus *cantaré-is*, 'you (pl.) will sing.'
2. In a first approximation, it can be concluded that stressed *-ré-* expresses future tense and indicative. We know that *-ré-* expresses indicative because the future form in the subjunctive (which is pretty unusual in contemporary Spanish) exhibits the unstressed segment *-re-* in its place: *canta-ré-mos* versus *cantá-re-mos*, 'that we will sing.' We know that *-ré-* expresses future because in the past form, it is substituted by *-ba-*: *canta-ré-mos* versus *cantá-ba-mos*, 'we sang.'
3. Also in a first approximation, canta- would be identified as a unit that carries the conceptual meaning of the word (that is, that tells us what kind of event or state we are talking about). We know this because it can be substituted by other verbs: *canta-ré-mos* versus *vivi-ré-mos* 'we will live' or *bebe-ré-mos* 'we will drink.'

Consequently, the word could be decomposed – SEGMENTED is the more technical term – as in (2), where each segment expresses different pieces of information, pending the examination of further contrasts which would refine the analysis and which we will discuss shortly.

(2) canta-ré-mos
a. canta -> verb
b. ré -> future indicative
c. -mos -> first person plural

With complications explored in Section Morphemes or Words?, many morphologists would call these segments, paired with meaning and grammatical information, MORPHEMES. In some theories, a central ingredient of morphological analysis is to provide the decomposition of words into morphemes, understood as the smallest units that, in themselves, carry meaning and grammatical information.

Given decompositions such as the one in (2), words can be divided in two groups: SIMPLE WORDS that consist of only one morpheme, and COMPLEX WORDS that contain two or more morphemes. (3) illustrates both classes with Spanish nouns.

(3) a. sal
'salt'
b. implica-ción
imply-ation
'implication'

Another aspect of morphology is to study how words that share some property are related to each other. Consider an English word like (4), a plural noun.

(4) paper-s

This word has at least two properties: it is a noun denoting a particular substance used to write on and it is plural; each one of these parts is associated with a morpheme.

A morphologist could compare this word to others that contain the information 'plural'; put more technically, to other words that have the LINGUISTIC FEATURE [plural]. This would imply comparing *paper-s* with *cat-s*, but also with a word like *women*,

where the morpheme *-s* is not present and instead a vocalic change has been used to mark [plural] (*woman* ~ *women*), a word like *fish*, where no apparent change has taken place (*fish* ~ *fish*), and perhaps even one like *people*, where apparently the expression of [plural] involved uses a different morpheme (*person* ~ *people*). Several questions would arise from this comparison, all of them relevant to morphology: (1) how many different ways does English have to express [plural] in nouns? (2) why do some nouns use one procedure, and others a different one? Are there principled reasons for this choice, or is it accidental and idiosyncratic? (3) what happens with nouns that, apparently, lack a plural form, like *thirst*? (4) and what about nouns which, in the plural, get a special meaning, and express different notions from those they express in the singular, like *savings*, understood as the money one has saved out of income? Ultimately, all these questions reduce to one: what are the conditions under which a noun can express the information [plural], and what are its effects?

Similarly, a comparison could be made on the basis of the first morpheme, *paper*, which would lead us to consider words such as *paper-work*, *wall-paper*, the verb *to paper* ('to cover something with paper') with its derived noun (*paper-ing*) and participle (*paper-ed*), etc. Here, other sets of questions would arise: (1) what are the kinds of words that we can build with the morpheme *paper*: nouns, adjectives, verbs…? (2) what is the meaning and form relation between these words? Why do we interpret *to paper* as 'to cover something with paper' and not, for instance, as 'to write something on paper'? (3) why do we need extra morphemes to make a verb out of a noun in, for instance, the pair *drama* ~ *dramat-ize* or *monopoly* ~ *monopol-ize*, but not on *paper* ~ *paper* or *chain* ~ *chain* 'to put a chain'? and (4) why is *-ing* used to build a noun from the verb *to paper*, and not *-ation* (*explan-ation*) or *-ment* (*govern-ment*), when other nouns coming from verbs use precisely these? Is this choice accidental or can it be captured by some generalization?

Given this basic comparison, the following is a nonexhaustive list of some crucial problems that morphology studies, all based on the observation that words relate to each other in meaning, function, and form:

1. Correspondence between category and grammatical information: given words of a class, what is the grammatical information that these words can express, and how is it organized? For instance: in a given language, what are the pieces of information that a verb carries, and how are they different from what a noun expresses? Do all languages differentiate nouns from verbs according to their morphology? Can a verb express aspect and not tense, or a pronoun person and not number, or gender but not number?
2. The shape of morphemes: why does a morpheme, sometimes, have to be pronounced differently and what is the relation between all these variants of a morpheme – called allomorphs? For instance: why does the morpheme *destroy* (*destroy-ed*, *destroy-ing*) alternate with *destruct-* (*destruct-ion*, *destruct-or*)? How do speakers determine which allomorph to use, and how are they distributed? How should we represent this alternation? Through a rule that produces one from the other, listing both morphemes as separate units, or from a common abstract morpheme that is pronounced differently under different conditions?
3. Derivation of meaning: how is meaning codified inside a word, how is it built from the internal components of that word, and how is it preserved, modified, or lost when other morphemes are added? For instance: how do we obtain the meaning 'that cannot be comprehended' from the morphemes *in-*, *comprehens-*, and *-ible* in *in-comprehens-ible*? Why can the verb *to seed* mean either 'to remove seeds' or 'to put seeds,' while *to nail* is only 'to put nails'? Why can we use *recital* to describe the event of *reciting poetry*, but not of *reciting the alphabet*?
4. Restrictions on Productivity: why are some morphemes unable to combine with many others, and how do speakers determine the kinds of words that can be built from a morpheme? For instance: why is it possible to build a noun denoting 'the person that does an action' with *run* (*runn-er*) or *murder* (*murder-er*), but not with *die* (**di(e)-er*)? Why can English make adjectives in *-able* from verbs like *analyze* (*analyzable*) or *break* (*breakable*), but not from *shine*, *exist*, *sleep*, or *sit*?
5. Morpheme selection: why are there different morphological procedures to express the same notion, as with [plural], and how do some words choose one, or several, of them? Why do we have *move-ment*, but not **mov(e)-ation*, while we allow both *govern-ment* and *govern-ation*, and what is exactly the difference between these two nouns that come from the same verb?

See, among many others, Spencer (1991), Harley (2006), Booij (2007), Lieber (2009), and Fábregas and Scalise (2012) for some recent introductions to morphology where more about these questions can be found.

Types of Morphemes

Morphemes are normally divided into two basic classes: affixes and roots. Roughly speaking, affixes are morphemes which have a fixed position inside the word and cannot form words by themselves or in combination with other affixes. Roots are morphemes with free position, which frequently can stand alone as words and can form a word with an affix. (5) is an example of an affix in English: it always appears to the right of a root and without a root does not form a word in English. (6) is a root. It can appear to either the left or the right of another root and it can form a whole word, a noun, without other apparent morphemes.

(5) -ish
  a. child-ish, *ish-child
  b. *This is too -ish.
  c. *sub-ish
(6) tree
  a. apple-tree, tree-house
  b. This is a tree.
  c. sub-tree

However, it is not always the case that a root corresponds to a word. In the Spanish verb *canta* (cf (1)) the root is *cant-*, which is not a word and which we obtain once we segment the affix *-a*, which marks that it is a verb belonging to a particular conjugation (as in *am-a* 'love' or *rob-a* 'steal'). In

languages whose morphology has affixes that mark the morphological class of the root, the smallest unit that can always appear alone as a word is the STEM, which is the combination of the root with the affix that marks its grammatical category, as *cant-a* or *am-a*.

Given their fixed order, affixes are further classified into the following main classes:

1. SUFFIXES, if they must follow the root, e.g., *-ish* (*whitish*);
2. PREFIXES, if they must precede it, e.g., *pre-* (*pre-war*);
3. INFIXES, if they appear inside the root, e.g., *bleedin'* in *abso-bleedin'-lutely*;
4. CIRCUMFIXES, if they consist of two parts, one before and one after the root, as in the German participle affix *ge-* … *-t* (*sagen* 'say' > *ge-sag-t*, 'said').

No equivalent distinction is made for roots. The reader will find throughout descriptions of the types of affixes according to their linear adjacency requisites, for instance, in Bauer (2003), as well as in the introductory texts presented in the previous section.

Morphology and Its Interfaces

Because of its nature, the grammatical aspects that morphology analyzes intersect with those explored in other linguistic disciplines. It shares with syntax the study of the grammatical information relevant to build phrases and sentences – tense, number, aspect, agreement, etc. – as well as the rules that combine objects with each other to form structures; with semantics, the study of how units codify meaning and how complex meaning is built by combination of smaller elements; with phonology, the question of how phonemes are combined inside units, the sound restrictions across morphemes, and how the segmental and prosodic properties of words are defined. Moreover, the properties of morphological units (words and affixes) are immediately relevant for psycholinguistics (especially lexical storage and lexical access), first and second language acquisition, pragmatics, and sociolinguistics; morphological research is a crucial part inside historical linguistics and language typology studies; it is obviously relevant to lexicography and other branches of applied linguistics dealing with words. In this section we would like to highlight two of the most relevant contact areas between morphology and other linguistic disciplines.

On the common ground between morphology and semantics, we find LEXICAL SEMANTICS, the study of how the meaning of roots and affixes is obtained, and whether the semantic contribution of a morpheme is internally structured or not. Some authors (Fodor and Lepore, 1998) claim that the meaning of any word is atomic – that is, it cannot be decomposed into smaller primitives that form a structure which accounts for what the word means – but the authors that believe that word meaning should be built from smaller elements are a majority. LEXICO-CONCEPTUAL STRUCTURES (Jackendoff, 1990) and QUALIA STRUCTURE (Pustejovsky, 1995) are examples of approaches where the meaning of morphemes is obtained through a hierarchical combination of smaller semantic primitives (such as *cause*, *become*, *animate*, *shape*, *function*, etc.). Lieber (2004) is a recent example of an attempt to use these structures to analyze morpheme combinations: morphemes come equipped with semantic structures which, in combination with those of the other morphemes in the word, determine properties such as the class of entities denoted by the word, its argument structure, or its aspectual information.

The study of the phonological operations that take place inside words is another important area of study in morphology. LEXICAL PHONOLOGY (Kiparsky, 1982; Mohanan, 1982) concentrates on the study of the special phonological processes that apply internally to a word, such as the rule of SPIRANTIZATION, that turns a dental stop into a fricative in the presence of certain affixes starting with a palatal sound (*naviga[t](e)* > *naviga[ʃ]-ion*). LEXICAL PHONOLOGICAL RULES apply inside words, typically across morpheme boundaries, and are IDIOSYNCRATIC: they allow for real exceptions. If we consider the combination of the morpheme *-al* (*verb-al*) with nouns ending in *-nt*, we see that frequently spirantization does not take place (*argumen[t]* > *argumen[t]-al*), except with some words (*presiden[t]* > *presiden[ʃ]-al*, where the orthography *presidential* represents the palatalization of /t/ with *-i-*). In contrast, POST-LEXICAL RULES apply inside words or between them and are expected to be general in the language; for instance, a post-lexical rule would be flapping in American English, which turns /t/ into [ɾ] in intervocalic position. Note that the rule does apply inside a word (7a) or between words (7b).

(7) a. edit > edi[ɾ]-ed
b. closet > … the close[ɾ] under a…

Recently, the study of lexical phonology in word formation has received revived attention; see Ito and Mester (2003), and especially Stratal Optimality Theory (Bermúdez-Otero, 2007, 2012, 2013).

There are other frequently studied phenomena on the interface between morphology and phonology. REDUPLICATION is a word formation process that involves repeating (part of) a root, as in Hungarian *néha* 'seldom' > *néha-néha* 'only sometimes.' INFIXATION, as hinted before, includes the cases where a morpheme is not completely linearized with respect to its base; here researchers have specially studied the interaction of the phenomenon with the position of stress and the number of syllables of the root. A final issue that has been studied are the asymmetries in the way in which different affixes integrate with its base. See Raimy (2000), Booij (2000), Yu (2007), Frampton (2009), and Kaisse (2005) for more information about these issues.

Inflection and Word Formation (Derivation and Compounding)

If we move now to morphological operations, it is traditional to distinguish between two types of processes: WORD FORMATION and INFLECTION. The first refers to the operations that, on the basis of another word, build a more complex one whose grammatical category, meaning, or other lexical properties have changed. (8) are all examples of word formation processes; in (8a), the second word is a noun, while the first was an adjective. In (8b), the meaning of the word has

changed: the complex word to the right does not simply denote an animal, but the offspring of an animal. In (8c), the elements that the verb requires to be used in a sentence change as a result of the morphological process – the first verb is intransitive, but the second requires a direct object. Any of these three types of changes is considered enough to claim that morphology has built a new word, distinct from the first one.

(8) a. clear > clear-ness
b. whale > whale-calf
c. wail > be-wail

In contrast, inflectional processes produce different forms of the same word, therefore without altering its grammatical category, its meaning, or other central lexical properties (9). (9a), from Russian, shows a noun that appears in a particular case, which depends on its syntactic function inside a phrase, but does not alter what the noun means or its grammatical category; (9b), from Portuguese, shows an adjective in feminine plural form, something which depends on its agreement with a noun; (9c), from Norwegian, shows a verb in past tense. None of these processes alter in any way the grammatical category of the word; in fact, the word could undergo those inflectional processes precisely because it belongs to a particular grammatical category, to begin with. The kind of entity they express remains unaltered (the same entity, the same property, and the same event). It is also worth noticing that normally an inflectional process marks a change that is triggered by syntax (like case assignment or agreement) or directly relevant to it (like the tense in which a sentence appears). Note also that inflection is typically performed through affixes, not through the addition of roots.

(9) a. stol-a
table-gen
b. branc-a-s
white-fem-pl
c. spis-te
eat-past

If we go back to word formation, further divisions are normally made here, depending on the kind of morphemes that are combined, affixes, or roots (cf the section 'Morphology and Its Interfaces').

A word-formation process that involves combining two roots (or two structures that contain roots) is a case of COMPOUNDING (10). If the morphemes combined with the root are all affixes, it is a case of DERIVATION (11).

(10) pick-pocket, air-conditioning, green-eyed, congress-woman, piano-bar
(11) re-build, whit(e)-en, class-ify, change-able, beauti-ful, pre-war, en-rich

Whether these three processes, inflection, derivation, and compounding, are really different phenomena that can be clearly differentiated from each other, however, is questioned by some morphologists. Scholars disagree with respect to whether the distinction between inflection and derivation actually exists; see Van Marle (1984), Haspelmath (1996), and Marantz (unpublished manuscript) for different approaches to this problem. There are also disagreements with respect to whether the division between compounding and derivation is clear; see Ralli (2010) for a summary.

Be it as it may, let us say a bit more about derivation. Given the importance of category change in a derivational process, derivational affixes are sometimes classified into NOMINALIZERS – if they form nouns (12), ADJECTIVIZERS – if they form adjectives (13), and VERBALIZERS – if they form verbs (14). The category of the unit they combine with is also used: DEVERBAL affixes are those that combine with verbs, e.g., *-able* (*dispos-able*); DEADJECTIVAL, those that combine with adjectives, e.g., *-ness* (*absurd-ness*); DENOMINAL, if they combine with nouns, e.g., *-less* (*tooth-less*). Thus, for instance, this last suffix would be called 'a denominal adjectivizer,' meaning it combines with nouns to produce adjectives.

(12) -ment, -(at)ion, -th, -ness, -ity…
(13) -ish, -less, -ful, -(i)ous, -al, -ic…
(14) -ify, -ize, -en…

It is important to remember, however, that category change is a sufficient, but not necessary, condition to characterize a process as derivational. Even when there is no category change, an affix can be considered derivational if the semantics of the base or other lexical aspects are altered (remember the *wail* ~ *be-wail* example). The reader will find recent summaries about word-formation processes in Lieber and Stekauer (2005, 2009) and Scalise and Vogel (2010).

Some Debates in Current Morphological Theories

We conclude this overview briefly presenting some of the main issues that are being debated in current morphological theories. The questions that we present now are, to some extent, orthogonal to each other.

Lexicalism and (Neo)constructionism

The first question has to do with whether morphology is a separate generative component of syntax. LEXICALISM (Halle, 1973; Booij, 1977; Lieber, 1981; Scalise, 1983; Ackema and Neeleman, 2004) argues that, next to syntactic rules, there are LEXICAL RULES which are responsible for word formation. In so-called strong lexicalist approaches, inflection is also performed through operations that take place in the lexicon, despite their obvious interaction with syntax. In these systems, the lexicon contains both a list of units and a set of operations that can apply idiosyncratically to only some units in order to build words. The output of these operations is an object that has all its relevant properties defined: grammatical category, argument structure, meaning, etc. Syntax, which operates after lexical rules, cannot manipulate the properties of words (The LEXICAL INTEGRITY HYPOTHESIS; see Lapointe, 1980). Consequently, the operations in syntax are determined by the properties of words, as defined in the

lexical component. (15) represents the relevant part of the lexicalist architecture of grammar.

(15) A Lexicalist architecture of grammar
List of items
↓
Lexical rules
↓
Syntax

In contrast, Neo-constructionist approaches – see Lieber (1992), Halle and Marantz (1993), and other authors working in the Distributed Morphology framework (Borer, 2005; Svenonius et al., 2009) – argue that word formation and inflection take place in the syntactic component, and thus that 'words' are in actuality also syntactic objects, a particular type of phrase which occasionally has special phonological or semantic properties (Julien, 2007). The lexicon would be just a list of stored items, and there would not be lexical rules. 'Lexical' properties, like grammatical category and argument structure, would emerge in syntax through the combination of roots with syntactic heads in different configurations. In contrast with Lexicalism, where syntax is conditioned by lexical information, in Neo-constructionist approaches, lexical information is defined by syntax. (16) presents the basic Neo-constructionist architecture, where the only generative component is syntax.

(16) List of items
↓
Syntax

Debates between these two approaches concentrate on how Neo-constructionism can explain the apparent effects of the Lexical Integrity Hypothesis, where syntax seems to be unable to access the internal structure of words, and how lexicalism can account for the many similarities between morphological and syntactic structures. See Marantz (1997), Spencer (2005), Williams (2007), and Bobaljik (2012) for different aspects of this debate.

Morphemes or Words?

Traditional morphology assumes that words can be decomposed into smaller units, morphemes, and in the section 'What Is Morphology?' we have also assumed it. However, this is far from established. Theories that decompose words into morphemes (and, therefore, treat morphemes as the basic units of morphological analysis) are called Item-and-Arrangement. They are opposed to theories where the basic unit of morphological analysis is the complete word and which are called Item-and-Process or Word-and-Paradigm (Aronoff, 1976; Anderson, 1992; Stump, 2001). For this second set of theories, morphology should not be viewed as a set of rules that combine morphemes into structures, but as a set of operations that associate a set of morphosyntactic and semantic properties with a particular word. (17) illustrates one possible way of representing the relation between the words beauty and beautiful in these models: there is an operation of adjectivalization that, applied to one word, gives the other.

(17) Adj (beauty) = beautiful

Thus, inside words there are no segmentable units that correspond to distinct pieces of information. In this theory, we cannot associate the property of [adjective] with the segment *-ful*; that segment is simply a phonological sequence that marks a change experienced by the word *beauty*.

The empirical support for theories without morphemes comes from three kinds of phenomena: (1) the fact that morphological decompositions sometimes must isolate recurrent segments which, however, cannot be associated with clear grammatical or semantic information (Berry morphemes), as in *in-stitute*, *pro-stitute*, *con-stitute*, *re-stitute*, where it would be extremely difficult to give a common meaning to the segment *-stitute*. In contrast, a word-based morphology would not encounter this problem, as it would be whole words that have a meaning, not their alleged morphemes; (2) the fact that sometimes there is no one-to-one mapping between information and segments. For instance, in some cases one segment codifies the information that otherwise would seem distributed between two sequences of segments (cumulative exponence), as in Spanish *canta* 'sing' > *canta-ste*, 'sang, 2sg' where *-ste* seems to contain information about tense and person agreement, which in other words would be expressed by different morphemes: *canta-ba-s*, 'sang, 2sg' where *-ba-* would express imperfective past tense and *-s* would express person agreement; (3) the fact that sometimes we can have changes in the grammatical information of the word without any change in its shape, as in conversion, which alters the grammatical category of the word apparently without adding any morpheme: English *dance* (noun) and *dance* (verb). Item-and-arrangement theories would have to postulate a phonologically silent morpheme in these cases, which is a problematic move for some authors; see the papers in Bauer and Valera (2005) for different takes on how to analyze conversion.

Lexical Listing versus Rules

The debate between listing and rules poses this question: how much information should be stored in the lexicon, as part of the idiosyncrasies that a speaker of a language must learn, and how much can be derived productively from abstract rules? For everybody, the lexicon must at the very least contain statements about how the phonological shape of an item is associated with its meaning; e.g., that the animal scientifically called 'Equus africanus asinus' is denoted by the sequence of phonemes /dɒŋkɪ/ in English, /buro/ in Spanish, etc. The questions are two: (1) what else should be listed? (2) if one believes that words have internal structure, in which cases a whole complex word has to be listed, and not its component morphemes?

Lexicalist theories tend to argue that all lexical units must be listed with information about their grammatical category, argument structure – if any, and purely morphological information such as its conjugation class or declension, whether it has irregular inflection, its co-occurrence restrictions with other units

and its position inside a complex structure. For instance, the lexicon would specify that *deep* is an adjective that, when turned into a noun, takes the morpheme *-th* (*dep-th*); in Spanish, *canta* 'sing' would be specified as a regular verb, from the first conjugation of the language; in English again, *-th* would be specified as a nominal affix, a suffix, and one that must combine with adjectives, but cannot follow other affixes (**tooth-less-th*, **child-ish-th*). In contrast, Neo-constructionist theories try to derive as much of this information as possible from general rules; for instance, in Distributed Morphology the grammatical category of a root is not specified in the lexicon, as it is derived from the syntactic context where the root appears (cf Arad, 2003 for other properties derived from here).

Some item-and-arrangement morphologists would argue that there would not be a lexical entry for a suffix like the nominalizer *-th* in the lexicon, and that instead, the words that contain it would have to be stored. Why? Because this affix has a very low PRODUCTIVITY, that is, there are very few roots that use it to nominalize, and speakers cannot build new nouns with *-th*: *dep-th*, *leng-th*, *warm-th*, *bread-th* are possible, but not **tall-th* or **cold-th*. Proposing a rule in this case would be unwarranted, and perhaps even useless, given the few cases that a speaker would have to memorize and store in her lexicon.

A second situation where listing of whole words is proposed is when the word shows unpredictable properties, which cannot be explained as the result of rules governing morpheme combinations. Take the word *birth*. Readers aware of the history of English might know that back in time this word was formed from the verb *bear* and the affix *-th*, with some then predictable phonological changes. Crucially, contemporary speakers are unaware of this, and it is doubtful that in their mind *birth* is related with *bear*; thus, in this case it is likely that a lexical listing solution would be used. Similar cases take place in Romance languages with Latin words. Even though the word *satisfacer* 'satisfy' was morphologically built in Latin by combination of the adverb *satis* 'enough' and the verb *facere* 'make, do,' it is unlikely that average speakers of Spanish relate this verb in any way with *hacer* 'make, do,' because in order to do so one should ignore unpredictable phonological and semantic differences. In general, rules determining morpheme combinations are only proposed when (1) they correctly restrict the set of morphemes to which it applies; (2) they can derive the grammatical information of the resulting word; (3) they derive the meaning of the resulting word from the meaning of the morphemes involved and how they are combined with each other; (4) if necessary, they account for the phonological changes experienced by these morphemes in the word, and (5) speakers can use those rules to productively build novel words.

Exponents and Morphosyntactic Features; Late Insertion

Another debated issue is whether the information stored is placed in one single list or should be distributed in different lists, which are accessed by different components of the grammar. In this second case, one influential proposal is that the MORPHOSYNTACTIC features associated with a morpheme must be stored in one list, to which syntax has access when building the structure, while the MORPHOPHONOLOGICAL information is in a second, distinct list. This is known as the SEPARATION HYPOTHESIS (Beard, 1995). In other words, we cannot properly talk of the nominal suffix *-ness* in *tall-ness*; we should talk about a nominal affix [N] which combines with adjectives – which is its morphosyntactic representation – and a morpho-phonological EXPONENT *-ness*, a suffix, that materializes or spells out that set of features under certain circumstances. This implies that morphemes have two sides: one that determines the properties of the units in syntax and one that determines how they will be phonologically expressed. The mismatches between grammatical information and morphological realization discussed in Section Morphemes or Words? can thus be treated under a new light (cf Ackema, 1995).

Some approaches go further, and propose that these two sides of the morpheme are accessed at different points. The morphosyntactic list is presyntactic, as it defines the properties of the units that syntax manipulates, and consequently determines the conditions under which a syntactic structure is licensed (e.g., that what we pronounce *-ness*, being a nominal element, could not combine with tense); the morphophonological list is postsyntactic, because, by hypothesis, the phonological properties of those items (such as whether they carry stress, end in a consonant, are trisyllabic, etc.) are not taken into consideration to build a syntactic structure. Thus, this information in inserted into the syntactic tree after it has been built; this hypothesis is known as LATE INSERTION (cf Halle, 1997). For some theories, this late inserted information includes also the purely morphological information about morpheme selection (for instance, that the exponent *mov(e)* takes the exponent *-ment* to nominalize, while *explain* takes *-ation*), declension or conjugation, morpheme ordering, etc.

Other authors (e.g., Borer, 2003) include also in a postsyntactic list the conceptual meaning of roots (for instance, that *donkey* denotes a certain animal), which is also unpredictable. This list would be distinct from the other two for two reasons: (1) if the first is relevant for phonology, this second one is only relevant to semantics as the meaning of exponents normally does not correlate with the phonemes involved in them, so they have to be kept in separate components; (2) the conceptual unpredictable meaning is associated with exponents, not to morphosyntactic features. The concepts expressed by *cookie*, *boson*, *dog*, *war*, *bottle*, *child*, and *rose* are all very different, but morphosyntactically they all correspond to the same kind of object: count nouns.

Note that each one of these three lists (morphosyntactic features, morphophonological exponents, and concepts) is relevant to each of the three major areas with which morphology interacts: syntax, phonology, and semantics.

Morphophonology

Hans Basbøll, University of Southern Denmark, Odense M, Denmark

Abstract

Morphophonology is the interaction between morphology and phonology, and these two linguistic disciplines are defined in Section Linguistic Disciplines and the Sign within a structuralist tradition of linguistics. Section Interaction between Phonology and Morphology: Three Examples presents three case studies of morphophonological interaction, departing from phonotactics (regular inflectional morphology of English), prosody (the Danish laryngeal prosody stød in its relation to word structure), and phonological variation (German and Danish stem change in plural formation). In section Morphophonemic Analysis, finally, the stages in a *morphophonemic analysis* are outlined, predominantly as part of a discovery procedure and within a structuralist tradition.

Introduction: Terminology

The term *morphophonology* is here taken in a broad sense, in agreement with its composite parts *morpho-* and *-phonology*, as covering the *interaction* between the linguistic components, or modules, *morphology* (cf Spencer and Zwicky, 1998) and *phonology* (cf Goldsmith, 1995). Accordingly, it is not to be understood as a separate linguistic component (such as morphology, phonology or syntax, for example). There are two further terms which are sometimes used in the same or in a closely related sense, viz. *morphonology* and *morphophonemics*. *Morphonology* (in German *Morphonologie*, French *morphonologie*) was the term which the leading founding father of Prague phonology used (Trubetzkoy, 1929, 1931). More recently, it has been the title of Dressler's (1985) book *Morphonology: the dynamics of derivation*. *Morphophonemics* has been a favorite term in American structuralism since *Menomini morphophonemics* by its leading founding father (Bloomfield, 1939). The term *morphophonemics* suggests more emphasis on the segmental building blocks in linguistic structure than the other terms which are neutral with respect to the distinction between segments and prosody.

Linguistic Disciplines and the Sign

The Linguistic Sign and Basic Linguistic Disciplines

The *sign* (French *signe*) is a key notion in structuralist linguistics, in the tradition following the Swiss linguist Saussure (1916). The sign is a unit – psychic and social – with two sides, viz. *content* (French *signifié* 'what is being signified'), or meaning, and *expression* (French *signifiant* 'what is signifying'), or sound. (Content and expression is the terminology of Hjelmslev (1943), and there is a comprehensive and complicated history of the linguistic sign, with linguistically central names like Peirce (e.g., 1965), and up to today's cognitive linguistics, e.g., in works by Langacker (1987).) One of Saussure's examples is the sign '*horse*' (French '*cheval*'). Its content is, according to Saussure, not the animal in blood and flesh – the animal is just being referred to – but the concept of a horse; nor is the expression the concrete sounds (neither articulatorily nor acoustically), the expression is an *acoustical image* (French *image acoustique*).

The relation between content and expression in a linguistic sign is, according to Saussure, *arbitrary* (French *arbitraire*: 'le signe linguistique est arbitraire'); i.e., there is *no natural connection* between the two: the relation is due to a social convention (normally not an explicit and conscious one, however). A sign like '*horse*' cannot be decomposed into smaller signs: it is one linguistic building block. Its content may be decomposed into smaller semantic elements (such as 'animal,' 'four-legged,' and so on); and its expression can be decomposed into smaller phonological elements (like initial /h/ and final /s/, etc.). But there is no general correspondence between the content elements and the expression elements (as there would be in the counterfactual state of affairs where /h/ would correspond to 'animal,' and so on). Such *minimal signs* (as '*horse*' in our example) are called *morphemes*. The arbitrarity of the sign is a characteristic of morphemes only, not of linguistic signs in general. When smaller signs are combined into larger and more complex signs, the relation between content and expression is no longer arbitrary, but *motivated*, viz. by the individual signs and by the construction(s) they enter into; e.g., when *black* and *bird* are compounded into *blackbird*, the meaning (of a particular ornithological species) is motivated, but not determined, by the meaning of *black* and *bird*.

The *basic linguistic disciplines* – 'language-internally,' excluding 'hyphen-disciplines' like socio(-)linguistics, psycho(-)linguistics and text(-)linguistics, for example – can be defined departing from the linguistic sign: *Semantics* is concerned with the *content*-side of language; and *phonology* with the *expression*-side of language (cf Section Phonology and Its Subparts). *Sign combinatorics* represents the traditional linguistic discipline *grammar*, divided into *syntax* and *morphology* (cf Section Morphology and the Word). When we depart from semantics and *transcend* the border between language-internal and language-external phenomena, we meet *pragmatics*. And when we transcend the border between language-internal and language-external phenomena from phonology, we meet *phonetics* (cf Section Phonology and Its Subparts). Thus both pragmatics and phonetics contain language-internal as well as language-external aspects. *Lexicon*, finally, as a linguistic

discipline is concerned with the *arbitrary* aspects of language, viz. of the relation between content and expression of morphemes (and partly words).

Morphology and the Word

Grammar can thus, from a strictly structuralist point of view, be characterized as the linguistic discipline which treats sign combinatorics, i.e., it is concerned with the *syntagmatic* (concerned with the linear order of elements in the speech chain) – as opposed to paradigmatic (concerned with choices on a particular position in the speech chain) – axis; grammar is subdivided into two (sub)disciplines, viz. *syntax* and *morphology*. The notion *word* is crucial to define the difference between those two: in syntax, the building blocks are words and the frame is (primarily) the sentence; and in morphology, the building blocks are morphemes and the frame the word. Therefore, the definition of a word is essential for morphophonology – the interaction between phonology and morphology.

The term *word* designates a central linguistic unit, and this term is, in distinction to most other units used in linguistic descriptions, by linguists, also a word used frequently by linguistically naïve speakers in general. This is related to the fact that the word is a unit with some psychological reality (and also to the fact that words are separated by space in orthography). The most appropriate linguistic definition of a word is by means of *distributional* characteristics: a word can occur in isolation, it can be moved around in an utterance, and its morphemes occur in a fixed internal order, all these criteria being interrelated and connected to its psychological reality. On the other hand, the word cannot be defined exclusively by semantic criteria – as suggested by the existence of lexicalized phrases, idioms (e.g., *kick the bucket*), complex lexical items, etc. – nor can it be defined cross-linguistically by phonological criteria. It is language-dependent to which degree word boundaries have a phonetic manifestation of any sort, i.e., languages differ typologically in this respect.

Phonology and Its Subparts

Phonology is the linguistic discipline concerned with the expression side of linguistic signs. (I disregard the analysis of written language in this article, and thus the issue of graphemes, letters, etc., cf Section Before Morphophonemic Analysis Can Start.) Whereas morphemes are the building blocks of morphology, *phonemes* are the primary building blocks of phonology. Phonemes are established by means of the *commutation test* using *minimal pairs*, cf Section Input Level to Morphophonemic Analysis: Phonemes. Phonemes are not linguistic signs, and they have no semantic content as opposed to morphemes, but they build up the expression of signs, together with prosodic elements. The basic subdivision of phonological units falls between *segmental* units, viz. phonemes – vowels and consonants – and *suprasegmental* units, i.e., *prosodies*. The latter category encompasses syllable prosodies and word accents (such as word stress, tonal word accents and the Danish stød, cf Section Prosody and Morphology: Danish Stød in Word Structure) and intonation. A particular subpart of phonology is *phonotactics*, i.e., combinatorics of phonemes, and this subdiscipline plays a pertinent role in morphophonology (see Dressler and Dziubalska-Kołaczyk, 2006 on 'morphonotactics'), cf Section Phonotactics and Morphology: English Regular Inflections.

Phonetics – the discipline concerned with language sounds (cf Section The Linguistic Sign and Basic Linguistic Disciplines) – is a crucial discipline for phonology, although it is not – within the structuralist linguistic tradition – considered a subdiscipline of phonology; but phonetics is a necessary condition for phonological analyses and descriptions that aim to be psychologically and physically realistic as well as testable, cf Section Nonchange of Phonetic Content between Levels: A Principle of Naturalness.

Nonchange of Phonetic Content between Levels: A Principle of Naturalness

Lemmas are lexical units. They can be divided into those which do not have several different expressions phonologically, but only one ('nonalternating lemmas') and 'alternating lemmas,' with more than one phonological expression (cf Section Phonological Variation and Morphology: Stem Change in German and Danish Plurals). For nonalternating lemmas, the phonological representation in the lexicon is, I shall propose, the (phonetic) surface form, disregarding only rather superficial phonetic details. This means, for example, that lemmas which do not enter into a particular morphological alternation – for example involving the Danish syllabic prosody stød, cf Section Prosody and Morphology: Danish Stød in Word Structure – are lexically specified accordingly (as having stød or not having stød). This is the null-hypothesis within the present framework. Thus, a lexical specification of a certain phonological property implies constancy of this property, irrespective of the morphological context, except for surface phonetic adjustments. A number of predictions with respect to alternations, in different paradigms and types of words, follow from this approach to the lexicon (see Basbøll, 2005, 2006). The fact that the symbols in the lexical representation are identical to symbols in the phonetic representation is an expression of the *naturalness principle* and holds not just for the relation between phonetics and phonology, but also in the morphology and the lexicon.

Interaction between Phonology and Morphology: Three Examples

Phonotactics and Morphology: English Regular Inflections

The typical pattern for regular inflectional morphology in English can be illustrated by the plural formation of nouns (similar principles apply to 3d person pres. tense, and (with *-ed*) to past tense). The ending is either [z], [s] or [ɪz], depending on the final segment of the stem, e.g., *hens*, *dogs*, *cats*, *busses* [henz dɔgz kæts ˈbʌsɪz]. Rather than listing all possible final segments of stems, the phonetic/phonological category of this segment can be represented through characterizations like 'voiced nonsibilant,' 'voiceless nonsibilant' and 'sibilant' – for the final segments combining with [z], [s] and [ɪz], respectively – typically using distinctive features

(for voicedness, sibilance, etc., as suggested above, but their exact inventory is controversial). Furthermore, the rules for the use of [z], [s] and [ɪz] can be simplified by being applied in a specified sequence.

What are the phonemes that are realized as [z], [s] and [ɪz] (as morphological endings, e.g., for plural)? According to the standard Bloomfieldian principle of 'once a phoneme, always a phoneme' (see Section Input Level to Morphophonemic Analysis: Phonemes), the phonemic analysis is straightforward: [z] is a realization of /z/, [s] of /s/ and [ɪz] of /ɪz/ (or /əz/, a difference which is insignificant here). According to a Praguian analysis, [z] and [s] would be analyzed differently: plural [z] – in examples like *hens*, viz. where the stem ends in a sonorant, e.g., a vowel or a nasal – would be a realization of the phoneme /z/ since in this position there is a contrast between [s] and [z], cf *buzz*, *bus* [bʌz bʌs]. In examples like *dogs*, on the other hand (where the stem ends in a voiced obstruent), plural [z] would not be a realization of the phoneme /z/, however, since there is no contrast to [s] in this position (e.g., *[dɔgs] is not a possible phonetic form in English). Similarly, plural [s] would not be a realization of the phoneme /s/ since there is no contrast to [z] in this position (e.g., *[kætz] is not a possible phonetic form in English). Plural [s], as well as plural [z] after obstruents, therefore realizes a neutralization product – an 'archiphoneme' – according to Praguian principles, i.e., a phonological unit which represents what is common to [s] and [z], without being phonologically specified for voicedness or voicelessness (even though [z] is phonetically voiced and [s] phonetically voiceless), cf Section Input Level to Morphophonemic Analysis: Phonemes.

Since the English plural ending [s] only occurs where [z] is phonotactically impossible, the following procedure (Basbøll, 1972, 2006) determines the choice of plural endings *without any reference to phonetic or phonological content* (such as segments, distinctive features, etc.):

1. Is [z] (phonotactically) OK? If yes: choose [z], if no: go to (2)
2. Is [s] (phonotactically) OK? If yes: choose [s], if no: choose [ɪz]

Illustrated with *hens*, *dogs*, *cats*, *busses* as examples:

1. [henz dɔgz] are (phonotactically) OK; but *[kætz], *[bʌsz]
2. [kæts] is (phonotactically) OK; but *[bʌss] not, so: [ˈbʌsɪz]

Since we know that speaker-hearers, including small children acquiring the language, are sensitive to phonotactical patterns in the language around them – even though we do not know the details of this mechanism – this is an interesting proposal not only because it is simple, but also from a psycholinguistic perspective. But where does the order [z] before [s] before [ɪz] come from? An obvious answer is frequency – as plural endings – in the language (and we know that frequency plays a role in language acquisition).

In addition to this completely regular pattern, English exhibits pl. forms identical to the sg. (as *sheep*), and a limited number of forms with the suffix *-en* (e.g., *oxen*, sg. *ox*), forms with stem change (as *men*, sg. *man*), and forms with a combination of stem change and suffix (as *children*, sg. *child*), cf Section Phonological Variation and Morphology: Stem Change in German and Danish Plurals. A morphophonologically interesting subpattern of stem change + suffix can be illustrated by *lives*, *loaves*, *houses* (sg. *life*, *loaf*, *house* – the latter pronounced with [s] whereas the plural form has intervocalic [z]). The stem change only concerns the final obstruent, it is a simple phonological change from voiceless (in the sg. stem) to voiced (in the pl. stem), and the principles of regular plural formation reviewed above apply to the pl. stem: [z] is selected as the plural suffix.

Prosody and Morphology: Danish Stød in Word Structure

The Danish *stød* is a laryngeal syllable rhyme prosody (somewhat resembling creaky voice). It only occurs in heavy (bimoraic) syllables which can be defined as those having a long sonority rhyme – a long vowel, or a short vowel followed by a sonorant consonant (e.g., a nasal or [l]) – and primary or secondary stress (in a 3 degrees of stress-system), see Basbøll (2005: 82–87, 265ff). Stød is contrastive, and there are many minimal pairs (i.e., pairs of words whose pronunciation is identical except for the presence or absence of *stød*, cf Sections Phonology and Its Subparts and Input Level to Morphophonemic Analysis: Phonemes), e.g., *musen* 'the muse,' definite form of the indefinite *muse* [ˈmuːsən ˈmuːsə] versus *musen* 'the mouse,' definite of the indefinite *mus* [ˈmuːˀsən muːˀs]. The grammatical distribution of stød is extremely complex, but it can be accounted for in Basbøll's Non-Stød Model. The relation between the syllable prosody stød, and word structure in Danish, is revealing for the interaction between phonology and morphology, viz. for morphophonology.

The Danish word has a three-layered structure as follows: {[(stem P1)P2]P3} where P1, P2 and P3 are positions for suffixes and where the position of the suffixes follows general principles of integration of suffixes into stems (in the word structure), see Basbøll (2005: 351ff). The minimal word, in '(…),' the basic word, in '[…],' and the maximal word, in '{…},' each define a *phonological domain*, i.e., a sequence within which certain phonological rules apply. The unmarked situation in the native vocabulary is that heavy (bimoraic, see above in Section Prosody and Morphology: Danish Stød in Word Structure) syllables have stød. There is, however, a principle of non-stød which applies to penultimate syllables in a minimal word, and to monosyllabic stems before a syllable in the basic word. Examples are the pl. form *huse* 'houses,' sg. *hus* [ˈhuːsə huːˀs] where *huse* has non-stød just like the monomorphemic word *muse* above (penultimate syllable of the minimal word); the past form *talte* 'spoke' versus the compounded verb with the same monosyllabic second part *udtalte* 'pronounced' [ˈtˢæːldə ˈuðtˢæːˀldə] (basic words [(*tal*) *te*] and [(*udtal*) *te*], respectively), i.e., a monosyllabic versus a polysyllabic stem before a syllable in the basic word. In all these cases, the position of the suffix in word structure is predicted by the model, P1 being the position for lexicalized (integrated) nonverbal suffixes (such as the plural suffix *-e*, the non-lexicalized pl. suffix being *-er*), and P2 for lexicalized verbal suffixes (such as the past tense suffix *-te*, the nonlexicalized past tense suffix being *-ede*). The definite suffix *-en* (in *musen* 'the mouse' above) always occurs on P3, thus stød is retained in the definite form of *mus* above since the following

syllable occurs outside the basic word. Accordingly, the distribution of stød and non-stød (in heavy syllables), a prosodic phonological phenomenon, cannot be predicted by the phonetic or phonological context alone, but crucially depends on grammatical structure, wherefore its description belongs in the realm of morphophonology.

Phonological Variation and Morphology: Stem Change in German and Danish Plurals

In both German and Danish, noun plurals are formed with either a suffix alone (incl. zero), or stem change alone, or a combination (incl. pl. = sg.), cf Section Phonotactics and Morphology: English Regular Inflections. The following three-way gradation of stem change, in the dimension of transparency versus opacity, based upon general phonological principles, has been proposed as a hypothesis applicable to languages exhibiting stem change as a morphophonological mechanism (Basbøll et al., 2011; Laaha et al., 2011):

1. '*No change*': no phonological change of the plural stem when compared to the singular stem (e.g., *bil, biler* 'car,' 'cars' [biːˀl, ˈbiːˀlɐ]). The category 'no change' does not preclude purely phonetic changes, however, cf Section Before Morphophonemic Analysis Can Start.
2. '*Weak change*': a *phonological change* of the plural stem which is either prosodic or due to an automatic segmental process. The category weak change, as far as segmental phonological changes are concerned (cf Section Phonology and Its Subparts), involves *changes in the string of concrete phonemes* – in a Bloomfieldian sense (cf Section Input Level to Morphophonemic Analysis: Phonemes) – but not in morphophonemes. For German this can be illustrated with the pl. *Bilder* 'pictures,' pronounced with [d], sg. *Bild* pronounced with [t]; these two sounds are in contrast initially (/t/ vs /d/), but finally there is no [d] due to the automatic segmental process of devoicing, and thus no final phoneme */d/ (cf Section Input Level to Morphophonemic Analysis: Phonemes); morphophonologically, on the other hand, there would be |d| in both sg. and pl. Whereas an automatic segmental change does not qualify as a phonological change, obviously, the reversal of such an automatic segmental process does, viz. German revoicing of the stem-final obstruent in the case of *Bild-Bilder* since it is not automatic, cf e.g., *Welt* 'world,' pl. *Welten*, both pronounced with [t].

   Prosodic changes can be illustrated by Danish stød changes (stød drop and stød addition, cf Section Prosody and Morphology: Danish Stød in Word Structure). The distinction between prosodic and segmental phonological changes is relevant, also psycholinguistically, as illustrated by the fact that Danes, when asked to reverse the syllables of the girl's name *Mona* [ˈmoːna] produce [ˈnæːmo] and not *[naˈmoː], thereby suggesting that the prosodic frame including stress and vowel length is stored separately from the string of segmental phonemes (Grønnum, 2007: 42–44).
3. 'Strong change': a segmental change of the plural stem which is *phonologically nonautomatic and primarily motivated by morphology*. Umlaut – also 'metaphony,' a change in stem vowel as in, e.g., English *mouse, mice* – in both German and Danish is a case in point. From a synchronic point of view, the relations between the singular and the plural stem in words with Umlaut are phonologically unmotivated (in German |a u o aw| in sg. (e.g., *Fass, Fluss, Knopf, Haus* [fas fluʊs knɔpf haws]) correspond to |ɛ y ø ɔj| in pl. (*Fässer, Flüsse, Knöpfe, Häuser* [ˈfɛsɐ ˈflʏsə ˈknœpfə ˈhɔɣ̞zɐ]), and in Danish |a a o ɔ| in sg. (e.g., *and, barn, fod, hånd* [anˀ bɑːˀn foðˀ hʌnˀ]) correspond to |ɛ ø ø ɛ| in pl. (*ænder, børn, fødder, hænder* [ˈɛnˀɐ bœɐ̯ˀn ˈføðˀɐ ˈhɛnˀɐ]). There is nothing in the phonological context – as against the morphological one – in today's languages that dictate the strong stem change. Furthermore, these stem changes apply to a limited (fewer in Danish than in German) subset only of morphemes, but very far from all, and there are obvious ambiguities in either direction (e.g., in Danish, sg. |a| can correspond to pl. |ɛ| or |ø|, and pl. |ø| to sg. |a| or |o|). All this shows that we are dealing, for strong stem change, with morphophonology, not phonology (cf Section From Phonemes to Morphophonemes: Introducing Morphological Relatedness).

Since stem change produces opacity which supposedly makes acquisition more difficult, no change, weak change and strong change, defined cross-linguistically as above, are predicted to delay acquisition in this order. Furthermore, from these hypotheses it is predicted that strong change in German will be less difficult for children than strong change in Danish since it is more homogeneous and has a higher type frequency (there are far more lemmas in German than in Danish representing each strong change). These predictions have been successfully tested in a large experiment with (Austrian) German and Danish children by Laaha et al. (2011).

Morphophonemic Analysis

Before Morphophonemic Analysis Can Start

The procedures surveyed below presuppose that the language is known to the phonologist undertaking the phonemic analysis. To *segment* the sound chain into words and to identify phonetic realizations as referring to the same word is no trivial task, due to inherent characteristics of the speech signal. The acoustic signal (in contradiction to the written language with spaces between words) consists of a continuous sound string with unclear or nonexisting markings of boundaries between syllables and such higher level units as words. Furthermore, the *variability* in the sound shape of individual words – both due to speaker characteristics and to the communication situation – makes it difficult to identify different acoustic realizations of the same unit as referring to the same linguistic entity, e.g., a word. Speakers can draw on prosodic cues such as stress, fundamental frequency (the main phonetic correlate of tone) and sonority (German *Schallfülle*, e.g., so that vowels, nasals and obstruents in that order have decreasing inherent sonority) in order to segment words in the sound chain, as well as on distributional – including phonotactical – patterns in the input.

The linguist's phonemic analysis is not undertaken directly on the basis of the sound chain itself – on concrete unanalyzed utterances – but departs from a phonetic transcription, i.e., a rendering of the continuous speech chain in terms of a string of phonetic symbols (for vowels and consonants), with or without diacritics (small marks added to phonetic symbols) – e.g. for aspiration, lowering, syllabicity, etc. – and with or without symbols for prosodic properties like stress, word tones, etc. Such a notation is discrete in the mathematical sense, with a finite and well defined number of symbols, e.g., taken from the International Phonetic Alphabet (IPA-symbols). But note that a huge amount of analysis, explicit and/or implicit, underlies any competent use of such a phonetic transcription system.

There is a fundamental distinction between a transcription of a concrete *token* (one individual instance, by a particular individual on a particular occasion) of speech – whether 'on-line,' e.g., in field work, or from tape etc., these two cases being clearly different – and a transcription of a pronunciation *type* (a single abstract pronunciation, representing an infinite number of possible tokens). The latter task demands a systematic transcription within explicit conventions and presupposes knowledge of the particular speech form. Only phonetic distinctions that either convey differences in meaning within the speech norm in question, or differences with sociolinguistic significance (e.g., sexual, sociological, regional or chronological), are typically rendered in a systematic phonetic transcription. As far as individual differences are concerned, level of *distinctness* ('register'), is a relevant parameter. For the procedures of phonemic analysis surveyed in this article, the phonetic transcriptions concern a high level of distinctness within a well defined speech norm. Furthermore, the stream of speech contains segmental and prosodic information intertwined, and the extraction of prosody from the segmental chain is anything but straightforward.

Input Level to Morphophonemic Analysis: Phonemes

In the phonemic analysis, in order to establish contrastive segments, the *commutation test* using *minimal pairs* is applied (cf Section Phonology and Its Subparts). Thereby both *contrastive segments* and *positions* in the sound chain are established as phonemically relevant entities. For example, taking the Danish word *sat* 'sat (ptc.)' [sad] as point of departure, the minimal pairs *sat*, *hat* 'hat' [had], *nat* 'night' [nad] establish [s], [h] and [n] as three different contrastive segments before [ad]; the minimal pairs *sat*, *sut* 'comforter (for babies)' [sud], *sit* 'his/her/its (refl. poss.)' [sid] establish [a], [u] and [i] as three different contrastive segments between [s] and [d]; and the minimal pairs *sat*, *SAS* '(the common Danish pronunciation of the *Scandinavian Airlines System*)' [sas], *sand* 'sand' [sanˀ] establish [d], [s], and [n] (with stød) as three different contrastive segments after [sa]. By the very same procedure, *three different phonologically relevant positions* are being established, i.e., there are exactly three positions ('places') in the sound chain [sad] where the segments can be contrasted with other segments, and this is established through the minimal pair or commutation test.

The analysis into phonemes is based upon a distinct pronunciation of single words in the norm chosen. The path from contrastive segments to phonemes is constituted by the following steps, observing the biuniqueness condition, viz. the principle that it is possible to infer both the phonemes from the contrastive segments, and also the contrastive segments from the phonemes (according to the phonological rules for the norm in question):

1. Phonetically closely related sounds which are not in contrast – in the sense that they form minimal word pairs, or potential minimal word pairs – are identified phonemically. Typically, two such sound symbols will be in complementary distribution – viz. each sound symbol only occurs in contexts of sounds where the other is excluded – but they might be free variants too (i.e., occur in contexts which are wholly or partly identical, but with no difference in meaning). The identification is based upon phonetic similarity not shared by any other sound segment in the phonetic notation. With reference to a well defined analysis of distinctive features, the sound symbols to be identified phonemically should possess a cluster of distinctive features not found together in any other sound. Examples of such identifications in Danish are [j] and [i̯] to /j/, and [ʁ] and [ʀ̥] to /r/.
2. Further identifications of phonetically closely related sounds which do not contrast in any specific context, can be made, still respecting the principle of biuniqueness, i.e., one and the same sound can be identified in two different ways phonemically, presupposing that the phonemic context is different. It is a condition for this kind of phonemic identification that the realization is motivated by a systematic phonological principle (such as, for Danish, vowel coloring by an adjacent /r/, pronounced as [ʁ] or [ʀ̥] dependent on position, in the direction of this /r/). An example of such an identification in Danish is the assignment of [ɛ] after a [ʁ] belonging to the same syllable ('tautosyllabic') and of [e] not after a tautosyllabic [ʁ] to the phoneme /e/ (e.g., *bredt*, *lidt* 'broad (neuter), little (adv.)' [bʁɛd led]), and the assignment of [a] after a tautosyllabic [ʁ] and of [ɛ] not after a tautosyllabic [ʁ] to the phoneme /ɛ/ (e.g., *ret*, *let* 'straight, easy' [ʁad lɛd]). On this procedure, including phonological fusion, i.e., bi(morpho)phonemic interpretation of a single phonetic, or phonemic, segment, see Basbøll (2006).

The relation between contrastive segments and positions (in the sound chain) are looked upon in very different ways by different schools or traditions of phonology (cf Fischer-Jørgensen, 1975). In my view there is still genuine insight to be gained from structuralist phonology, and from combining an eclectic structuralist approach with more modern ways of considering phonology-phonetics and phonology-morphology-lexicon interrelations.

At one end of the scale we find the strict (post-) Bloomfieldians (Bloomfield, 1933; cf Bloch and Trager, 1942; Joos, 1957) with the tenet 'once a phoneme, always a phoneme,' i.e., when a contrastive segment has been established in one position, it is phonemic in all positions. When /p/ and /b/ are established as contrasting allophones (word-)initially in German, for example (cf the minimal pair *Pein* 'torment' pronounced with initial [p] and *Bein* 'leg' with initial [b]), the sound [p] (word-)finally must be an allophone of /p/,

even though the sound [b] does not occur (word-)finally wherefore there can be no contrast in this position either; the phoneme /b/ is then said to be *defectively distributed*. A consequence of this analysis is that *Lob* 'praise,' *Lobe* (dat.) [lo:p], [ˈlo:bə] exhibits a morphological alternation between /p/ and /b/ (syllable-initially). For example, the stop in *Rad* 'wheel' [ʁɑ:t] and *Rat* 'council' [ʁɑ:t] are pronounced identically word-finally (and hence syllable-finally), but enter different morphological alternations, cf *Rade* 'wheel (dat.)' [ˈʁɑ:də] and *Rate* 'council (dat.)' [ˈʁɑ:tə]. According to the Bloomfield-school, this can be analyzed so that the phoneme /t/ word-finally can alternate with either of the phonemes /t/ or /d/ syllable-initially. Both of the morphophonemes |t| and |d| are thus realized by the phoneme /t/ in word-final position.

In Prague phonology (cf Trubetzkoy, 1939), there would be *neutralization* word-finally in German, i.e., a particular phonemic entity, an *archiphoneme*, would occur in the position of no contrast, viz. a segment which is phonetically voiceless but has no specification for voicing phonologically and is thus neither a /p/ nor a /b/, but something which is common to the two (cf Section Phonotactics and Morphology: English Regular Inflections). Such an *incompletely specified segment* is given a separate phonological notation, e.g., /P/ (as in *Lob* [lo:p]) for a segment which is phonetically a voiceless plosive like initial /p/, but is not in contrast (opposition) to a /b/ (which is in contrast to /p/ initially). A consequence of this analysis is that *Lob*, *Lobe* (dat.) [lo:p], [ˈlo:bə] exhibits a morphophonological alternation between /P/ (word-finally and hence syllable-finally too) and /b/ (syllable-initially).

From Phonemes to Morphophonemes: Introducing Morphological Relatedness

Phonetic and phonemic transcriptions rely exclusively on input from sound. By contrast *morphophonemic* transcriptions (between vertical strokes) involve also morphological information. Heuristically, two phonemes can be identified morphophonemically if they occur in parallel positions in different forms of the same morpheme – e.g. in different inflectional forms belonging to the same paradigm – if it applies to a significant set of morphemes in a systematical way. A Danish example would be /j/ in *spøge* 'make jokes' [ˈsbø:i̯ə] ~ [ˈsbø:ɪ], and /g/ in its past participle *spøgt* [sbøgd], which may be considered as representing the same morphophoneme |g|. There is no claim of biuniqueness (cf Section Input Level to Morphophonemic Analysis: Phonemes) between morphophonemes and sound chain, viz. the same phoneme in the same phonemic context can represent different morphophonemes – as /v/ [ʋ̯] in *sagfører* 'barrister' [ˈsɑʋ̯fø:ɐ] represents the morphophoneme |g|, cf *føre sag* 'litigate' [føɐ ˈsæ:ˀɪ̯], contra |v| in *savklinge* 'saw blade' [ˈsɑʋ̯kʰleŋə], cf *sav* 'saw' [sæ:ˀʋ̯].

The morphophonemic analysis should make phonological patterns simpler and more general, e.g., with simpler phonotactics and more general principles of realization. An example from Danish could be: |p|, |t|, |k| are always realized as plosives, whereas |b|, |d|, |g| have variable realizations as either plosive or approximant, depending on their position in the phonological syllable.

In Danish, the position just before a stressed (nonnative) suffix, like *-i*, *-ik*, *-at*, *-ere* is revelatory for the morphophonemic identity of consonants undergoing consonant gradation. Thereby the morphophonemic analysis of the syllable-final phonemes /b/, /d/, /g/, /ð/ leads to the following alternations and identifications 1 through 5. The generalizations only pertain to a segment in word-final position alternating with a segment in morpheme-final position just before a stressed (nonnative) suffix beginning with a vowel.

1. Syllable-final /d/ alternates with syllable-initial /t/, both representing the morphophoneme |t| (e.g., in *vat* 'cotton wool' [vad], *vattere* 'quilt' [vaˈtˢeːˀɐ] and *demokrat* 'democrat' [demoˈkʰʁɑːˀd], *demokrati* 'democracy' [demokʰʁɑˈtˢiːˀ]);
2. syllable-final /g/ alternates with syllable-initial /k/, both representing the morphophoneme |k| (e.g., in *lak* 'lacquer, n.' [lɑg], *lakere* 'lacquer, v.' [laˈkʰeːˀɐ] and *patriark* 'patriarch' [patˢʁiˈɑːg], *patriarkat* 'patriarchate' [patˢʁiɑˈkʰæːˀd]);
3. syllable-final /b/ alternates with syllable-initial /p/ in some (nonnative) words, thus representing the morphophoneme |p| (e.g., in *mikroskop* 'microscope' [mikʰʁoˈsgoːˀb], *mikroskopi* 'microscopy' [mikʰʁosgoˈpʰiːˀ]);
4. syllable-final /b/ alternates with syllable-initial /b/ in some (nonnative) words, thus representing the morphophoneme |b| (e.g., in *hydrofob* 'hydrophobe' [hydʁoˈfoːˀb], *hydrofobi* 'hydrophobia' [hydʁofoˈbiːˀ]);
5. syllable-final /ð/ alternates with syllable-initial /d/ in (nonnative) words, thus representing the morphophoneme |d| (e.g., in *abbed* 'abbot' [ˈabeð], *abbedisse* 'abbess' [abeˈdisə]).

Morphophonemes as Candidate Lexical Segments

Section Morphophonemic Analysis until now was an attempt to characterize morphophonemic transcriptions *from below* ('bottom-up'), i.e., from sound via phonemes to morphophonemes, as part of a *discovery procedure* (cf Harris, 1951). But morphophonemes can also be considered candidates for *underlying segments* in the lexicon.

Whereas the morphophonemes are derivable from the surface structure, by means of a bottom-up procedure, *lexical segments* are the units posited as underlying. There is not a unique string of morphophonemes corresponding to every string of phonemes or sounds, but rather there may be different solutions, so to speak, to this discovery procedure, depending on which sets of morphological alternations are to be accounted for.

The relation between phonemes and morphophonemes is not biunique: whereas it is in general possible in Danish – for the main speech norm chosen here – to derive the phonemes of a given word form from the morphophonemes, by means of phonological principles and mechanisms, the opposite is not true: Such a biuniqueness presupposes an explicit exhaustive enumeration of the word forms that are considered formally related and nonsuppletive (i.e., not phonologically unrelated forms, such as English *be*, *is*, *was*). In many cases, in many specific phonemic contexts, several morphophonemes correspond to the same phoneme, and vice versa: the same morphophoneme corresponds to several phonemes.

From the point of view of the addressee, and not least of the person acquiring the language, there will be several candidates for lexical segments in many cases, and an ongoing change in the lexical representations can be expected, according to (increased) awareness of morphophonological relations, i.e., morphological relations paired to their phonological realizations.

A decision on such issues depends on whether we are talking about

1. hypotheses about speakers, i.e., about psycholinguistics and psychological reality; or
2. methodological principles for the analysis, regardless of any relation to the behavior of real speaker-hearers.

In the case of (1), speakers' knowledge and awareness of orthography must be expected to play a substantial role in alphabetized cultures, and this issue should be subjected to empirical investigation. If we are to speculate about the psychological reality for speakers of Danish of two equally possible morphophonemic transcriptions |braːv| and |braːg| for Danish [bʁɑːˀʋ̥], which may mean either 'brave' or 'crash' (neither word enters into morphological alternations which might reveal the underlying identity of the stem-final consonant), it may be relevant, for example, that *brav* 'brave' is written with the letter *v*, finally, that occurs initially in words pronounced with [v] (/v/), and the homophonous *brag* 'crash' with the letter *g* that occurs initially in words pronounced with initial [g] (/g/), cf *vi*, *gå* 'we,' 'go' [vi], [gɔːˀ]. Furthermore, different speakers' ideas of relatedness between word forms – whether historically founded or not – may be relevant for their lexical representations, and also this matter should be investigated empirically. These issues represent the strong sense of *morphophonemes* as *candidate lexical segments*.

In the case of (2), *naturalness* can be chosen as a methodological guideline for the relation between different levels (see Section Nonchange of Phonetic Content between Levels: A Principle of Naturalness): the correspondence between the contrastive segment [X] and the phoneme /X/ is more natural than between [X] and /Y/, and the correspondence between the phoneme /X/ and the morphophoneme |X| is more natural than between /X/ and |Z|. This is not just a question of arbitrary labels: both contrastive segments and phonemes have phonetic content, even though the degree of abstraction is not the same; and morphophonemes as well have phonetic content – and can be analyzed in terms of distinctive features, and so on – even though they also encode information about morphological alternations which may have consequences for the phonetic content.

Concluding Remarks

Morphophonemic *analysis* in the narrow sense is a 'bottom-up'-procedure from phonemes, e.g., established from sound by means of the commutation test, to morphophonemes. But the morphophonemic analysis in the broad sense – inversely – can also proceed the other way round, viz. as a 'top-down'-procedure, called *synthesis* in the narrow sense (e.g., in Hjelmslev's (1943) terminology). In Section Morphophonemes as Candidate Lexical Segments, a perspective of synthesis in this sense was taken, viz. when morphophonemes were considered as candidate lexical segments. From that perspective, a phonological description – to avoid the term 'analysis' in order not to confuse the narrow and the broad sense of this term – can be given from lexical segments until phonemes, and further on via contrastive segments to phonetic segments. Such a description involves realization principles or rules of some sort, e.g., as those used in different versions of generative phonology in the broad sense, and somehow recalling basic descriptive principles behind Bloomfield's (1939) *Menomini morphophonemics*.

Note

Sections Phonotactics and Morphology: English Regular Inflections and Morphophonemic Analysis are based upon Basbøll (2006). The IPA-transcription of Danish follows Basbøll (2005), however without diacritics for voicelessness (Danish [b d g] are voiceless). I am indebted to Nina Grønnum for numerous valuable stylistic and other suggestions.

Mortality and the HIV/AIDS Epidemic

This article is a revision of the previous edition article by A. Palloni, volume 15, pp. 10058–10061, © 2001, Elsevier Ltd.

Abstract

The knowledge base on HIV/AIDS has improved vastly since the disease first emerged as a global threat to public health some 30 years ago. While then an HIV diagnosis was a certain death sentence, it is now widely considered a manageable chronic disease owing to advances in medicine. Together with successful prevention efforts, these advances have dramatically altered the mortality impact of the epidemic. This article reviews the global epidemiology of HIV/AIDS, takes stock of the present state of the epidemic, describes the evolution of patterns of AIDS mortality, and discusses some of the challenges facing the global response to HIV/AIDS into the future.

Introduction

In 1981, physicians in the United States noticed a disturbing increase in deaths to previously healthy, young gay men due to rare infections and cancers that had seldom been fatal in the past (CDC, 1981). Not long thereafter, doctors in Eastern Africa noted cases of a new, fatal wasting disease. They agreed that whatever had caused these deaths had compromised their patients' immune systems so severely that their bodies were unable to fight infections that ordinarily posed no serious threat to healthy people. Doctors remained unsure as to what exactly was causing the condition, thus they labeled it the 'Acquired Immune Deficiency Syndrome' (AIDS).

In 1984, two separate teams of scientists isolated the viral agent responsible for crippling the immune systems of AIDS patients; it was eventually named the Human Immunodeficiency Virus (HIV) (Coffin et al., 1986). HIV infects and ultimately leads to the destruction of CD4 white blood cells (also called T-cells) that are critical to the body's ability to mount an immune response to viruses and bacteria. A healthy person has between 500 and 1500 CD4 cells mm^{-3} of blood. In the absence of medical intervention, HIV spreads throughout the body and the concentration of CD4 cells in the infected person's bloodstream falls below 200, leaving him or her vulnerable to opportunitstic infections and, ultimately, death (Moore and Chiasson, 1999).

Tremendous advances achieved over the ensuing decades have saved countless lives by enabling individuals, families, and communities to prevent HIV transmission while also prolonging the lives of those already infected. Advances in public health, for example, have included large-scale education campaigns, condom distribution, and needle exchange programs that enable people to protect themselves from HIV. Medical advances have brought a suite of antiretroviral (ARV) drugs that slow the progression of the disease and are highly effective at preventing HIV infection in infants, who account for the majority of new infections among children. The emergence of AIDS invigorated social movements toward gender equality and gay rights, yielding significant advances in confronting the biases, stereotypes, and stigma that amplify vulnerability to HIV infection. The epidemic also gave rise an unprecedented global political response to a shared health threat: it inspired the establishment of a dedicated United Nations agency, UNAIDS, to combat the disease and political declarations of the United Nations General Assembly, including the 2001 Declaration of Commitment on HIV/AIDS and two Political Declarations on HIV/AIDS adopted in 2006 and 2011, as well as billions of dollars in philanthropy, international aid, and domestic health spending.

Despite these advances, UNAIDS estimates that since 1990 around 33 million people have died from AIDS-related causes (UNAIDS, 2012). Indeed, the HIV/AIDS epidemic has dealt a powerful blow to hundreds of years of sustained progress in human survival. It is one of only a handful of diseases that have produced worldwide epidemics, thus achieving pandemic status. Prior to the emergence of HIV/AIDS, virtually all of the world's populations had made progress through the epidemiologic transition, a process characterized by the waning occurrence of large fluctuations in mortality rates attributable to frequent famine and infectious disease outbreaks, and the growing relative importance of diseases associated with aging, such as cardiovascular diseases and cancers. Among the countries most highly affected by AIDS, the disease halted progress through that transition. It has produced sharp increases in mortality rates, especially among adults aged 15–49 years, and it has erased decades of gains in life expectancy. It has killed a sizable proportion of the working-aged population in some countries, with important demographic, social, and economic consequences for this generation and the next.

This article begins with a summary of HIV/AIDS epidemic dynamics, including the modes of transmission and factors that determine whether an HIV epidemic can emerge and be sustained. The section Global Overview of the HIV/AIDS Epidemic provides an overview of the global HIV/AIDS epidemic and explains how incidence and prevalence have varied across regions and over time. The section AIDS-Related Mortality describes the evolution of the mortality impact of HIV, illustrating how the epidemic has shaped the age patterns of mortality and trends in the life expectancy in highly-affected populations. The article concludes by identifying some of the challenges that remain to be tackled in the global response to the epidemic into the future.

HIV/AIDS Epidemic Dynamics

HIV is relatively difficult to transmit compared to other infectious diseases such as influenza and tuberculosis, and even other sexually transmitted infections, such as gonorrhea or syphilis (Abu-Raddad et al., 2008). For HIV transmission to take place, a susceptible person must come into close contact with certain body fluids of an infected individual. Only blood, semen, vaginal secretions, and breast milk can carry quantities of the HIV virus sufficient for transmission to occur. Thus the main modes of HIV transmission are sexual intercourse, injecting drugs using contaminated needles, and from mother-to-child during pregnancy, delivery, or breastfeeding. While medical transfusions of blood containing HIV contributed to the spread of HIV during the early years of the global epidemic, donor blood supplies are now screened routinely and in most countries transfusions no longer carry the risk of HIV transmission that they once did (Takei et al., 2009).

The term 'efficiency' refers to the probability that a virus is transmitted during a given contact between an infected person and a susceptible person. Mother-to-child transmission (also called 'vertical' transmission) is the most efficient mode: on average, in the absence of any preventive intervention, an infant born to an HIV-positive mother has around a 30% chance of acquiring HIV (Rollins et al., 2012). Both injecting drug use and sexual intercourse are far less efficient modes of HIV transmission. The average per-contact probability of transmission among injecting drug users (IDUs) who share needles and other injecting equipment is estimated around 0.8% (Hudgens et al., 2001). Transmission probabilities associated with sexual intercourse can vary widely, depending on the type of intercourse, whether the susceptible male partner is circumcised, and the presence of co-infection with other sexually transmitted infections (STIs). Receptive anal intercourse is the most efficient means of HIV transmission through sexual activity (about 1.7% per contact), followed by receptive penile–vaginal intercourse (0.08% per contact), and insertive penile–vaginal intercourse (0.04% per contact) (Boily et al., 2009; Baggaley et al., 2010). Male circumcision reduces the likelihood of infection by around 60% per sexual contact (Auvert et al., 2005; Bailey et al., 2007; Gray et al., 2007), while the presence of STIs such as gonorrhea, chlamydia, or herpes simplex virus, amplifies sexual transmission efficiency by five times, on average (Boily et al., 2009). Across all modes of transmission, the viral load (the concentration of the HIV in the body fluids) of the infected person is a powerful determinant of the transmission efficiency. Probabilities of transmission are amplified several times over when the viral load is very high, as occurs during the first weeks following the initial infection and again during the late stages of disease (Royce et al., 1997). Despite the low transmission efficiency, sexual intercourse is the most common mode of HIV transmission because of the large proportion of the population at risk (UNAIDS, 2012).

In order for an HIV epidemic to emerge and become sustained in a population, each new infection must, on average, lead to at least one additional new infection. This concept is known as the 'reproductive rate of infection' and is denoted by R_0 (Anderson and May 1991). When R_0 is less than 1, the epidemic cannot sustain itself and eventually dies out. In any given population, R_0 is determined by three factors: (1) the average rate of contact between infected and susceptible persons, (2) the average duration of infection, and (3) the efficiency of transmission (Anderson and Garnett, 2000). In the case of HIV, the duration of infection is long – a median of around 11 years from initial infection to death in the absence of drug treatment for HIV (Ghys et al., 2007) – but transmission tends to be inefficient. Thus, an HIV epidemic can grow and sustain itself only when the rate of contact between infectious and susceptible persons is sufficiently high.

In the early years of a country's HIV epidemic, the rate of contact between infectious and susceptible persons in the general population is low: in nascent epidemics adult HIV prevalence is very low – less than 1% infected among persons aged 15–49 years – and sexual exposures are rare. But in certain key population subgroups, rates of contact between infectious and susceptible persons may be high enough to give rise to localized epidemics. One key population subgroup historically associated with local epidemics is men who have sex with men (MSM), among whom sexual practices were associated with greater transmission efficiency (Royce et al., 1997). Commercial sex workers (CSW) also constitute a key population in the epidemiology of HIV: their frequency of sexual exposure, exposure to multiple partners who themselves have other partners, high prevalence of STI co-infection, low capacity to negotiate condom use, and high rates of exposure to sexual violence leave CSW particularly vulnerable to HIV infection. IDUs are a third key population with heightened vulnerability to HIV infection, again because of their frequent exposures to higher efficiency modes of transmission. When epidemics are sustained among key populations but transmission among the general population remains rare and adult HIV prevalence is less than 1%, a country is said to have a 'concentrated' HIV epidemic.

An HIV epidemic becomes 'generalized' when transmission becomes sustained outside of the key populations and adult HIV prevalence grows to exceed 1%. In generalized epidemics, heterosexual intercourse is the dominant mode of HIV transmission (UNAIDS, 2012). Some characteristics that may facilitate the emergence of a generalized HIV epidemic include high rates of contact between the general population and key populations that are experiencing high HIV prevalence; low coverage of protective factors such as male circumcision or condom use; and high prevalence of factors that enhance transmission efficiency, such as STI co-infections or concurrent sexual partnerships (having relationships with two or more sexual partners that overlap in time, thus increasing the likelihood of contact between an infectious person and a susceptible person during the highly infectious period following the initial infection) (Morris et al., 2010).

The past few decades have witnessed enormous advances in the prevention and treatment of HIV/AIDS, dramatically improving the capacity of individuals, families, communities, and societies to mitigate the medical, social, and economic impacts of HIV/AIDS. The first large-scale interventions to have been prioritized on a global scale focused on education. Disseminating accurate information about HIV/AIDS and how it is (and is not) spread was viewed as key to encouraging protective behaviors and uptake of voluntary testing, as well as to reducing stigma and discrimination surrounding the diagnosis. The role of education in slowing or reversing the growth

of HIV epidemics has not been well established, although household surveys in many countries indicate that young people have been delaying initiation of sexual activity and using condoms correctly and consistently at greater rates (UNAIDS, 2012). Among key populations in particular, information, education, and communication campaigns have focused on reducing the number of sexual partners, promoting condom use and, among IDUs, encouraging users to demand and access sterile injecting equipment.

Other advances in HIV/AIDS prevention have taken the form of medical interventions. Early on, ecological evidence strongly suggested that male circumcision was protective against HIV infection (Bongaarts et al., 1989; Caldwell and Caldwell, 1994). Later, three clinical trials confirmed that observation: circumcision reduced the likelihood of vaginal-to-penile transmission of HIV by as much as 60% (Auvert et al., 2005; Bailey et al., 2007; Gray et al., 2007). The World Health Organization (WHO) and UNAIDS thereafter recommended that voluntary medical male circumcision be promoted as an effective measure toward HIV prevention (in conjunction with correct and consistent condom use) in populations with high rates of heterosexual transmission of HIV and low prevalence of male circumcision (WHO/UNAIDS, 2007). By the end of 2011, just 1.3 million voluntary medical circumcisions had been performed for HIV prevention among men in high prevalence areas (UNAIDS, 2012), but it was hoped that new less invasive technologies will improve the availability and access to the procedure in the future (WHO/UNAIDS, 2011).

Among the most important advances in HIV/AIDS medical science has been the development of a class of drugs, called antiretrovirals (ARV), that effectively slow the progression of the disease, suppressing viral loads often to undetectable levels and allowing CD4 counts to rebound. The first ARVs were introduced in the mid-1990s and by 2010, more than 20 such drugs had been licensed (Vella et al., 2012). WHO guidelines, updated in 2010, recommend that adults and adolescents with HIV begin a course of antiretroviral therapy (ART) once the CD4 count falls to 350 cells mm^{-3} (WHO, 2010a). Once a patient begins an ART regimen, it must be continued for life. At the end of 2011, an estimated 8 million people in low- and middle-income countries were receiving ART, representing 54% of those in need according to the 2010 WHO guidelines. For children who acquire HIV infection in the period surrounding their births or in the first 2 years of life through infected breast milk, the WHO advises that ART begin immediately irrespective of the CD4 count (WHO, 2010b). In 2011, just 28% of children in need of pediatric ART were receiving it. In 2013, the WHO again revised its guidelines to recommend that ART be initiated even earlier, beginning when a patient's CD4 counts drops below 500 cells mm^{-3} (WHO, 2013).

Not only do ARVs dramatically prolong the lives of people living with HIV, but new evidence indicates that these drugs are highly effective at reducing the probability of HIV transmission. The drugs are so effective at reducing mother-to-child transmission that UNAIDS has set a target of zero new HIV infections among infants globally by 2015 (UNAIDS, 2010). Among heterosexual partners, treating the infected partner with ART can reduce sexual transmission efficiency by as much as 96% (Cohen et al., 2011), thus the WHO has recommended that persons living with HIV be offered ART irrespective of CD4 count if in a relationship with an uninfected partner (WHO, 2012a, 2013). While some studies have suggested that ARVs can be effective in preventing HIV transmission if taken prophylactically by the uninfected partner, recent trials have produced disappointing results in part as a result of participants' poor adherence to drug regimens (WHO, 2012b).

Global Overview of the HIV/AIDS Epidemic

To achieve an accurate picture of the number of people living with HIV and AIDS mortality is extremely difficult. Around half of people living with HIV worldwide do not know their status (UNAIDS, 2012) and most AIDS deaths occur in areas that lack reliable death registration (Mathers et al., 2005). To estimate the numbers of people living with HIV (the number of prevalent HIV infections) at the country level, analysts rely on a combination of surveillance and surveys. Sentinel surveillance is used to monitor HIV prevalence – the proportion of the population infected with HIV – in populations at risk for HIV. In concentrated epidemics, sentinel surveillance monitors HIV prevalence among the key populations experiencing HIV epidemics, which may include MSM, IDUs, or CSW, depending on the context. For generalized epidemics, sentinel surveillance monitors HIV prevalence among pregnant women attending clinics for antenatal care. In addition to sentinel surveillance, many countries have conducted household surveys, such as Demographic and Health Surveys (DHS), and included biomarkers that can be used to obtain estimates of adult HIV prevalence. The estimates from household surveys are then considered together with those obtained through sentinel surveillance in order to fit an epidemic curve for each country. In partnership with national statistical offices, UNAIDS produces updates of HIV prevalence for 155 countries every 2 years. Estimates of HIV incidence – the rate at which new HIV infections occur – are then derived from models suited to the prevalence estimates, and estimates of AIDS deaths are predicted from the combined incidence and prevalence estimates, taking into account mortality rates from other causes and the coverage and effectiveness of ART (Stanecki et al., 2012).

HIV prevalence estimates obtained from both sentinel surveillance and household surveys are subject to some degree of uncertainty since they do not cover the entire population. Sampling errors associated with prevalence estimates, combined with additional uncertainty introduced by the models applied to derive incidence and mortality from prevalence data, mean that there is considerable uncertainty surrounding the national estimates produced by UNAIDS. To account for that uncertainty, UNAIDS publishes lower and upper bound estimates for HIV prevalence, incidence, and AIDS deaths.

Figure 1 shows UNAIDS estimates of the number of adults and children living with HIV globally over the period 1990 through 2011. The shaded area represents the associated lower and upper boundaries that reflect the uncertainty introduced by the data and modeling procedures. At the end of 2011, an estimated 34.0 million people were living with HIV worldwide with associated uncertainty ranging from 31.4 to 35.9 million.

Figure 1 UNAIDS estimates of the number of people living with HIV worldwide, with associated uncertainty, 1990–2011. Data source: UNAIDS Report on the Global AIDS Epidemic – 2012.

This figure represented a 20% increase since the end of 2000, when an estimated 28.3 million (uncertainty bound from 26.1 to 31.1 million) people were living with HIV. The annual growth rate in the number of people living with HIV globally has declined markedly over the course of the epidemic. This rate averaged 14.8% in the early 1990s, but has remained well under 2.0% since 2003 (data not shown).

The continuing increase in the number of people living with HIV globally masks the marked progress achieved in averting new infections and preventing death among those living with HIV. **Figure 2** plots UNAIDS estimates of the numbers of new HIV infections and AIDS deaths globally, along with associated uncertainty bounds, for the period 1990 through 2011. From the figure of 1.9 million (1.6 to 2.1 million) new HIV infections globally in 1990, the annual number of incident infections rose to a peak of 3.5 million (3.4 to 4.1 million) in 1997 and has declined fairly steadily thereafter to an estimated 2.5 million (2.2 to 2.8 million) new HIV infections in 2011. In the absence of changes in mortality, such a reduction in the numbers of new cases would be expected to lead to a decline in the number of people living with HIV. That the number of prevalent cases has instead continued to grow is testament to the improved survival of people living with HIV following uptake of ART. At the end of 2005, the year global AIDS deaths peaked at 2.3 million (2.1 to 2.6 million), ART was reaching less than 2 million people in low- and middle-income countries, but by 2011, 8 million people were receiving ART, representing 54% of the estimated number of people needing it (UNAIDS, 2012).

The geographic distribution of HIV/AIDS impact has been highly uneven (**Figure 3**). At the end of 2011, 56 countries were experiencing generalized HIV/AIDS epidemics with prevalence among the population aged 15–49 in excess of 1%. Among these, 39 countries were located in sub-Saharan Africa, home to 69% of people living with HIV and 71% of AIDS deaths in 2011 (UNAIDS, 2012). In three countries located in Southern Africa – Botswana, Lesotho, and Swaziland – adult HIV prevalence exceeded 20%.

Outside of sub-Saharan Africa, the region with the next highest HIV prevalence is the Caribbean, where 1.0% (0.9–1.1%) of adults aged 15–49 were living with HIV at the end of 2011. Generalized epidemics were noted in the Bahamas, Jamaica, Haiti, and Trinidad and Tobago. In Asia, only Thailand was experiencing a generalized epidemic in 2011, with adult HIV prevalence at 1.2% (1.1–1.2%). The only European country with HIV prevalence greater than 1% in 2011 was Estonia, at 1.3% (1.1–1.6%). Concentrated epidemics – where HIV prevalence was less than 1% in the general population aged 15–49, but greater than 5% among key populations – were more widely distributed geographically in 2011.

Most countries experiencing generalized epidemics have seen the rates at which new infections occur decline in recent years. In sub-Saharan Africa overall, the adult incidence rate fell from its high of 0.86% (0.78–0.92%) to 0.38% (0.35–0.42%) in 2011. In the Caribbean region, the adult incidence rate declined from 0.18% (0.13–0.25%) in 1990 to 0.06% (0.04–0.07%) in 2011. However, evidence points to stalled or reversed progress in some countries, such as Uganda, where the adult incidence rate is estimated to have risen slightly in recent years: after having declined from 1.34% (1.12–1.55%) in 1990 to 0.62% (0.52–0.69%) in 1998, it increased thereafter to reach 0.84% (0.75–1.00%) in 2011. A comparison of results from DHS conducted during the same time period points to increasing prevalence of multiple sexual partners in 12 months and decreasing condom use as possible explanations for the heightened incidence in Uganda (UNAIDS, 2012).

Recent growth in HIV incidence in some regions gives cause for concern that some countries with concentrated epidemics could eventually develop generalized epidemics. UNAIDS notes that the number of new infections in the Middle East and North Africa grew by more than 35% between 2001 and 2011, while some evidence pointed to increasing incidence in Eastern

Figure 2 UNAIDS estimates of the number of people newly infected with HIV and AIDS-related deaths worldwide, with associated uncertainty, 1990–2011. Data source: UNAIDS Report on the Global AIDS Epidemic – 2012.

Figure 3 Adult HIV prevalence (%), 2011. Data source: UNAIDS Report on the Global AIDS Epidemic – 2012.

Europe and Central Asia as well. The agency has identified nine countries with increasing epidemics, which it defines as having experienced a 25% or greater increase in the rate of adult HIV incidence between 2001 and 2011: Bangladesh, Georgia, Guinea-Bissau, Indonesia, Kazakhstan, Kyrgyzstan, Philippines, Republic of Moldova, and Sri Lanka.

Some populations saw growth in the overall numbers of people newly infected with HIV, even as the incidence rate remained stable or declined. This phenomenon is attributable to growth in the population aged 15–49. For the world as a whole, the rate of HIV incidence among those aged 15–49 in 2011, at 0.06% (uncertainty ranging from 0.06 to 0.07%), was equivalent to the incidence rate in 1990, but the annual numbers of adults newly infected with HIV grew over that same period from 1.7 million in 1990 to 2.2 million in 2011. This growth corresponds to the growth in the global population aged 15–49 from 2.7 billion in 1990 to 3.7 billion in 2011 (UN-DESA, 2011). In the United Republic of Tanzania, a decline in the adult HIV incidence rate from 0.64% (0.59–0.70%) in 2000 to 0.59% (0.51–0.68%) in 2011 was insufficient to stop the growth in the numbers of new infections each year. Persistent high fertility throughout the latter half of the twentieth century had produced sustained growth in the population at risk for HIV infection from 15.6 million in 2000 to 21.1 million in 2011 (UN-DESA, 2011), resulting in an increase in the numbers of new infections from 97 000 in 2000 to 120 000 in 2011 (UNAIDS, 2012).

AIDS-Related Mortality

Regional Trends in AIDS-Related Mortality

While the annual number of AIDS-related deaths globally peaked in 2005 and has declined thereafter following declining incidence and increasing ART coverage, regional trends in AIDS-related mortality show important differences. Sub-Saharan Africa, which accounted for 78% of global AIDS-related deaths in 2005 and 71% in 2011, has driven the global trend. The region achieved a 33% decline in total AIDS-related deaths between 2005 and 2011 (Table 1). Within sub-Saharan Africa, Botswana, Burundi, Côte d'Ivoire, Ethiopia, Kenya, Namibia, Rwanda, Zambia, and Zimbabwe each achieved reductions in annual AIDS-related deaths of more than 50% during that period (UNAIDS, 2012).

South Asia was the region with the second-highest number of AIDS-related deaths in 2011 with 250 000 deaths and while the region had achieved a reduction in the number of AIDS deaths since 2005, at 14% the pace of decline was slower than in sub-Saharan Africa. Four regions saw increases in annual AIDS-related deaths between 2005 and 2011: Eastern Europe and Central Asia, East Asia, the Middle East and North Africa, and North America. Both the Caribbean and Oceania were estimated to have even larger proportional reductions in AIDS-related deaths than sub-Saharan Africa: the number of AIDS-related deaths was halved in the Caribbean between 2005 and 2011, while Oceania achieved a 43% decline.

Age Patterns of AIDS-Related Mortality

Unlike many other infectious diseases that disproportionately affect children and the elderly, the mortality impact of AIDS is most pronounced among adults in the prime of their lives. Approximately 86% of AIDS deaths occur among adults aged 15–59 (Bongaarts et al., 2011), while 14% of AIDS deaths are among children aged 0–14. Proliferation of ART is anticipated to shift AIDS mortality to later ages into the future.

Figure 4 plots the age-specific mortality rates (m_x; natural log scale) for Southern Africa (which includes Botswana, Lesotho, Namibia, South Africa, and Swaziland) over 5-year periods spanning the region's HIV/AIDS epidemic. During the period 1990–95 – when HIV prevalence was rising, but deaths had not yet had a significant impact on all-cause mortality – the age pattern of mortality from all causes was typical: high in infancy, declining throughout childhood, rising in adolescence, and increasing steadily thereafter through the adult ages. By 1995–2000, excess mortality due to AIDS was visible in the mortality rates of adults of aged 15–49. From adolescence, age-specific mortality rates rose sharply among those in their 20s and leveled off among those in their 30s at a higher level than was observed for the same age range 5 years earlier. The mortality impact of AIDS is magnified even more in 2000–05, with higher age-specific mortality rates among those

Table 1 AIDS-related deaths in 2005 and 2011 and percentage change, by region

	2005		*2011*		
Region	*Deaths*	*(Uncertainty bound)*	*Deaths*	*(Uncertainty bound)*	*Percentage change 2005–11*
Global	2.3 million	(2.1–2.6 million)	1.7 million	(1.5–1.9 million)	−26
Sub-Saharan Africa	1.8 million	(1.6–1.9 million)	1.2 million	(1.1–1.3 million)	−33
South and South-East Asia	290 000	(270 000–310 000)	250 000	(190 000–340 000)	−14
Eastern Europe and Central Asia	76 000	(58 000–100 000)	92 000	(63 000–120 000)	21
East Asia	39 000	(27 000–56 000)	59 000	(41 000–82 000)	51
Latin America	60 000	(36 000–93 000)	54 000	(32 000–81 000)	−10
Middle East and North Africa	20 000	(15 000–25 000)	23 000	(18 000–29 000)	15
North America	20 000	(16 000–26 000)	21 000	(17 000–28 000)	5
Caribbean	20 000	(16 000–23 000)	10 000	(8200–12 000)	−50

Figure 4 Age-specific mortality rates, Southern Africa, 1990–95 to 2005–10. Data sources: United Nations, Department of Economic and Social Affairs, Population Division, 2011; World Population prospects: The 2010 Revision.

in their 20s, 30s, and 40s than had been observed 5 and 10 years earlier. By 2005–10, elevated death rates shifted to later ages, reflecting both reduced HIV incidence that shifted the age distribution of people living with HIV toward older ages and expanding coverage of ART. While trends in mortality from non-AIDS causes have influenced these all-cause mortality rates as well, much of the recent pattern of adult mortality in Southern Africa is attributable to the impact of AIDS (Reniers et al., 2011).

The evolution of the mortality impact of the epidemic is also evident in the changing survival probabilities among Southern Africa's birth cohorts. Figure 5 charts the percentage of selected birth cohorts who were still alive at each age (a dashed line indicates survival prospects projected after 2010). Survivors of the cohort born in 1950–55 were in their mid-40s at the peak of HIV incidence. They experienced relatively high mortality in childhood, but moderate mortality rates in adulthood such that median age at death (the age by which half of the cohort has died) is estimated at around 65 years. The cohort born 10 years later in 1960–65 was in their 30s during peak incidence and had better survival than their 1950–55 counterparts to age 50, but thereafter saw diminished survival prospects and a median age at death closer to 60. The cohort born in 1970–75 has been especially hard hit by AIDS-related mortality. They were in their 20s during peak incidence and while their survivors are still relatively young – in their late 30s and early 40s at the time of this writing – they are projected to have a median survival of only

Figure 5 Proportion surviving by age, selected Southern African birth cohorts. Data sources: United Nations, Department of Economic and Social Affairs, Population Division, 2011; World Population prospects: The 2010 Revision.

around 50 years. The survival benefits of ART are anticipated to become evident among Southern Africa's birth cohort born in 1980–85 with a projected median survival of close to 55 years. If current projections prove accurate, the birth cohort of 1990–95 will reap the benefits of both ART and reduced HIV incidence, with their median age at death rebounding to become similar to that of the 1950–55 birth cohort. Such projections are subject to a high degree of uncertainty, however, and rely on assumptions about the future course of the HIV/AIDS epidemic, coverage and effectiveness of ART, and levels of mortality due to other causes. For details regarding the assumptions about the future of the HIV epidemic and coverage and success of interventions, including ART, see United Nations, Department of Economic and Social Affairs, Population Division (2011, 1).

Impact of HIV/AIDS on Life Expectancy at Birth

The life expectancy at birth is a common indicator used to summarize the level of mortality over all ages for a given point in time. It represents the average number of years a hypothetical cohort of individuals would live if subjected throughout their lives to the age-specific mortality rates of a time period. For most of human history, life expectancy increased only very slowly as frequent events like famine and infectious disease epidemics shaped mortality trends. Public health advances of the nineteenth century, however, brought rapid improvements in survival, which were bolstered further with the introduction of vaccines to prevent the spread of many formerly common communicable diseases. As a result, the past two centuries have witnessed tremendous gains in life expectancy, beginning first in the more developed regions and then spreading to developing regions as well. The shift in the predominant causes of death that accompany increasing life expectancy – away from communicable diseases and nutritional conditions and toward the noncommunicable diseases associated with aging – is known as the epidemiological transition (Omran, 1971).

For the countries hardest hit by HIV/AIDS, the epidemic has stalled or even reversed progress through the epidemiological transition, as evidenced by recent trends in the life expectancy at birth. In some countries, such as Botswana where adult HIV prevalence exceeded 20% in 2011, AIDS effectively wiped out the gains achieved in life expectancy since the 1960s (**Figure 6**). Life expectancy in Botswana dropped from 64 years in the late 1980s to 49 years in the early 2000s, before recovering somewhat after 2005 with the rollout of ART. In countries where expansion of access to treatment has not proceeded as quickly, such as South Africa, the recovery in life expectancy has occurred more slowly. While life expectancy in countries with smaller epidemics has been less affected, stalled progress through the epidemiological transition coincident with the emergence of HIV/AIDS is evident. Jamaica, Nigeria, and Thailand have all experienced slowed progress in life expectancy, despite adult HIV prevalence below 5%.

New evidence suggests that expanded coverage of ART has the potential to dramatically improve the expectation of life in populations highly affected by AIDS. Bor et al. (2013) completed the first population-based study of mortality change after widespread ART rollout, focusing on a rural region of South Africa where HIV prevalence approached 30%. They estimated an 11.3 year gain in the life expectancy at age 15 over the 4 year period from 2003 to 2007 following widespread uptake of ART. The study indicated that even without universal coverage of ART, dramatic increases in life expectancy were achievable with widespread access to treatment.

Figure 7 Population by sex and age group, 2010, and counterfactual in the absence of HIV/AIDS, Southern Africa. Data sources: United Nations, Department of Economic and Social Affairs, Population (thousands) Division, 2011; World Population prospects: The 2010 Revision.

Impact of HIV/AIDS on Population Size and Age Structure

In some highly-affected countries, the population size and age structure has been noticeably altered by AIDS-related mortality. Figure 7 displays a population pyramid for Southern Africa, with the size of each bar representing the size of the population in each age group, with children at the bottom of the pyramid and the elderly at the top. The dark shaded bars represent the actual population size in the region in 2010, while the light extensions of the bars indicate what the population size would have been if AIDS-related mortality had never occurred. According to this counterfactual, in 2010, Southern Africa's population of 57.8 million people was 8% smaller than it would have been in the absence of HIV/AIDS. The population deficit is most evident among those aged 30–54 in 2010, among whom AIDS mortality has been most severe: the population in this age group was 16% smaller than it would have been if the epidemic had not occurred. Their absence is felt among the families, communities, and economies left behind. An estimated 17.3 million children worldwide in 2011 had lost one or both parents to HIV/AIDS and 88% of them lived in sub-Saharan Africa (UNAIDS, 2012).

The Future of the AIDS Epidemic

Predicting the future of the HIV/AIDS epidemic has proven a futile endeavor. In the early years of the epidemic some scientists were confident of the imminence of a vaccine, yet 30 years later vaccine trials have repeatedly produced disappointing results. By the early 2000s, forecasts had grown dire, with warnings of 65 million AIDS-related deaths between 2002 and 2020 (UNAIDS, 2002), more than 10 million infected in China by 2010 (UN Theme Group on HIV/AIDS in China, 2002), and population decline in some of the worst affected countries (United Nations, 1991). The reality, while still critical, proved far less calamitous. Credit is due, in part, to education campaigns that have given people the knowledge and tools they needed to protect themselves, and to new drug discoveries that have saved an estimated 14 million life years in low- and middle-income countries alone thus far (UNAIDS, 2012), while simultaneously averting countless new infections.

Continuing the current downward trends in global HIV incidence will depend on success in reducing the prevalence of risk behaviors while increasing access to and use of the proven tools that prevent the transmission of HIV. Among the most effective prevention tools is ART, which also prolongs the lives and improves the well-being of people living with HIV. Despite substantial progress in delivering ART to those who need it, these efforts continue to be outpaced by the number of new HIV infections. In sub-Saharan Africa, a record 2.3 million people were added to treatment programs over the 2-year period 2010–11, but the region saw 3.7 new HIV infections during that same time (UNAIDS, 2012). Increasing uptake of prevention and treatment, in turn, hinges on the success of efforts to promote education and gender equality, while eliminating stigma and discrimination.

Selected additional challenges to the continued reduction of AIDS-related mortality include the high risks of tuberculosis associated with HIV infection and the tenuous sustainability of HIV/AIDS programs. Tuberculosis accounts for nearly one in four AIDS-related deaths and while the number of tuberculosis deaths to people living with HIV has fallen by 25% since 2004, significant challenges remain (UNAIDS, 2012). Tuberculosis

screening, voluntary HIV testing, and early ART delivery need to be scaled up since treatment is known to be effective at preventing tuberculosis acquisition and mortality.

Many of the countries most affected by HIV/AIDS also have insufficient domestic resources to devote to epidemic response and the health system more generally. Their heavy reliance on international investments raises concern surrounding the fragility of existing HIV/AIDS programs. While domestic investment in the AIDS response has increased, international donor support accounted for more than half of the 2011 investment in 26 of 33 sub-Saharan African countries (UNAIDS, 2012). The latest efforts focus on integrating HIV/AIDS prevention and treatment into comprehensive health care services, including sexual and reproductive health care, to improve the sustainability of programming into the future.

Abstract

The biodemography of mortality aims to explain observed age patterns and time trends in mortality rates from the biological point of view. It integrates knowledge about biological factors and mechanisms affecting mortality rates with demographic information and approaches using unifying theoretical concepts, methods of mathematical modeling, and statistical analyses. The future of this research area depends on the progress in understanding factors and biological mechanisms involved in regulation of aging, and their connections to mortality. These include progress in experimental fields and advances in understanding evolutionary forces shaping the age pattern of mortality.

The biodemography of mortality deals with the integration of knowledge about biological factors and mechanisms involved in forming age patterns and time trends of mortality rates by combining demographic concepts and approaches with biological information, concepts, and methods in the analysis of mortality data. The typical pattern of age-specific mortality rates exhibits an initial spike at birth followed by a decline during infancy and early childhood (ontogenescent part) followed by an increase during adolescent and later ages (senescent part). The declining and increasing parts reflect the effects of distinct interacting components of the age-specific mortality rate that are usually studied separately. These interacting components contribute to a broader phenomenon of mortality correlations at different ages, across populations, and over time (Vaupel et al., 1998). Factors that have been considered as possible contributors to such correlations include evolutionary forces, *in utero* environments, and early life conditions, among others (*see* Early Life Influences on Health and Mortality in Adulthood). Despite intensive study, no general consensus has been reached on the nature of the relationships between these two components of the mortality curve.

Although studying mutual connections between the two components has scientific merit, most attention during the last decade has focused on the senescent (increasing) component. This attention was motivated by the substantial progress achieved in manipulating rates of individual aging in laboratory animals raising the possibility of extending life and reducing disease prevalence in humans (Sierra et al., 2009). To understand whether and how such goals could be achieved for humans, one has to better understand the biological machinery involved in the regulation of aging-related declines in health, well-being, and physiological functioning, and the connections between such declines and health and survival outcomes.

Biodemographic studies of the senescent component of human mortality allow for efficient use of integrated knowledge from relevant research fields including epidemiology, genetics, sociology, gerontology, environmental sciences, population genetics, etc., for maintaining human health, well-being, and longevity. There are many interesting biodemographic ideas, concepts, and methods relevant to understanding mortality. This article provides a selective account of important historical steps in the development of this research field and illustrates how the integration of demographic and biological knowledge and data contributed to progress in the field.

Frailty Models

Survival experiments with large populations of laboratory animals provided evidence that the senescent component of the age-specific mortality rates in a number of species increases exponentially over most of the adult age range (following Gompertz's curve) but, at the upper end of the adult age range, it decelerates, levels off, or even declines. The results of these analyses were summarized in Vaupel et al. (1998). The downward deviation from the Gompertz curve has been explained by the presence of hidden (unobserved) heterogeneity in the chances of death. The demographic frailty model (Vaupel et al., 1979) employed an unobserved 'fixed frailty' variable to describe individual differences in susceptibility to death; the fixed frailty concept provided a convenient tool for analyzing mortality rates over the entire range of adult ages. The use of such models was a substantial step forward in understanding the forces shaping cohort mortality curves and in elucidating the roles of compositional changes in this process.

Although the fixed frailty models improved the descriptions of late-age mortality curves, they provided little information about the biological mechanisms influencing the mortality rates. Moreover, it was found that the class of fixed frailty models was not distinguishable from a class of models with randomly changing heterogeneity variables (Yashin et al., 1994). This observation indicated that additional information is needed to better understand the forces involved in regulation of the mortality rates. One way of adding such information was to introduce explanatory variables (observed covariates) into the fixed frailty models. Such models then treated hidden frailty as a random effect and corresponding studies were focused on estimation of effects of observed covariates on survival in the presence of hidden frailty. It was shown that the presence of hidden frailty influences the

estimates of the effects of observed covariates on mortality risks. It was found that, when ignored, the presence of unobserved frailty diminishes estimated effects.

An important class of extended frailty models used information on survival in related individuals (e.g., twins, sibs, and other relatives). For a number of such models (which differ in their frailty distributions), the multivariate survival function was described in a semiparametric form. A remarkable property of such semiparametric models was that one did not need to specify a parametric form for the baseline hazard rates. These hazard rates could be estimated semiparametrically from bivariate or multivariate survival data. Multivariate survival models were used in analyses of the heritability of individual susceptibility to death, as well as the heritability of mortality by cause (Wienke, 2010). The fact that extreme longevity runs in families suggests the high potential for further development of multivariate survival models to study factors and mechanisms affecting exceptional survival in families, including genetic factors.

Biodemographic Ideas in Genetic Analyses of Mortality

The genetics of aging, longevity, and mortality has become the subject of intensive analyses, ranging from studies of candidate genes to genome-wide association studies (GWAS) (Nebel et al., 2011) that involve hundreds of thousands to millions of genetic variants (i.e., single-nucleotide polymorphisms). However, many estimates of genetic effects on longevity in GWAS have not reached genome-wide statistical significance (using the Bonferroni correction for multiple testing) and many findings remain nonreplicated.

Possible reasons for slow progress in this field include the lack of a biologically based conceptual framework that would drive development of statistical models and methods for genetic analyses of data, the presence of hidden genetic heterogeneity, the collective influence of many genetic factors each with small effects, the effects of rare alleles, and epigenetic effects; as well as molecular biological mechanisms regulating cellular functions. In addition, researchers studying the genetics of human aging and longevity tend to underestimate the role of demographic information and biodemographic ideas in genetic analyses. The use of demographic mortality data and models of hidden heterogeneity in mortality helped improve the accuracy of genetic estimates in genetic centenarian studies. These analyses were able to detect the nonmonotonic (U-shaped) age trajectories of genetic frequencies corresponding to intersections of mortality rates for carriers and noncarriers of the respective genetic variants. The existence of such trajectories was confirmed in later studies. Alternative hypotheses describing possible mechanisms responsible for such age patterns of genetic frequencies (intersections of mortality rates) were discussed in Yashin et al. (2001) and Bergman et al. (2007). The U-shaped patterns of genetic frequencies indicated that the effects of the corresponding genetic variants on mortality risk changed from harmful to beneficial during the life course. This property suggested that some genetic risk factors contributing to the mortality increase early in life are likely to be found in the genomes of long-lived individuals. This conclusion has been confirmed in a number of recent studies of human aging and longevity. The use of demographic information and models in analyses of data on genetically heterogeneous cohorts allowed researchers to compare the age patterns of mortality rates for carriers and noncarriers of candidate alleles and genotypes. Such comparisons were not possible using data on genetic frequencies alone. These methods were further extended in Arbeev et al. (2011). Recent genetic analyses of health-related traits revealed that many genes affecting life span and health span do exhibit pleiotropic effects.

Evolution of Aging, Health, and Mortality

The possibility of evolutionary origins of common aging-related diseases in situations where disease susceptibility alleles demonstrate deleterious or slightly deleterious effects were discussed in Pritchard (2001) and Reich and Lander (2001). Their results indicated that the alleles affecting life span must show pleiotropic associations with health span, duration of unhealthy life, and mortality rates by cause. Under other population genetics scenarios (Di Rienzo, 2006), neutral genes can also be involved in the origin of common diseases. Since such genes have little or no effect on fitness, their associations with health-related traits are likely to be manifest in various trade-offs. The evidence for negative correlations between select diseases has been provided in Stallard (2002) and Ukraintseva et al. (2010), among others. The existence of dependencies among diseases suggests the possibility of common genetic backgrounds for groups of health-related traits. The results of recent studies confirmed the existence of pleiotropic associations of certain genes with health traits (Jeck et al., 2012). Thus, in addition to pleiotropic associations of genes between life span and health-related traits, such genetic associations can also be found among groups of health-related traits.

In parallel with demographic efforts focused on developing and implementing models of survival in heterogeneous populations, researchers in the field of aging recognized the crucial role of aging-related changes in biomarkers that influence the chances of death. In contrast with Gompertz's assumption about a rapid exponential decline in the 'vitality function' with increasing age, the reviews of physiological studies of aging carried out in the middle of the last century showed that physiological parameters characterizing many biological human capacities tended to decline almost linearly with age.

Strehler and Mildvan's Model of Mortality and Aging

To reconcile a linear decline in biological capacity with exponential increases in the rate of mortality, Strehler and Mildvan (1960) proposed a model of aging and mortality (SM-model). In this model, mortality was viewed as a response of an aging organism to the random fluctuations of energy demands. According to the SM-model, the death rate at a given age was proportional to "the frequency of stresses which surpass the ability of a subsystem to restore the initial conditions" at that age. They showed that, under such an

assumption, the exponential increase in mortality (Gompertz's curve) results from the linear decline in vitality. The model allowed them to explain the negative correlation between the two parameters of the Gompertz curve (SM-correlation) observed in empirical studies of the age patterns of mortality rates. The rectangularization pattern of survival improvement during the first half of the last century in developed countries was in accordance with the SM-correlation, as predicted by the SM-model (*see* Mortality: The Great Historical Decline). These changes were linked to a decline in the average magnitudes of stresses experienced by subsequent population cohorts. The rectangularization pattern of survival improvement was also exhibited in subgroups of individuals ordered by the number of longevity alleles that they carried (Yashin et al., 2012). Since the environmental conditions in each such group remained the same, the SM-model linked better survival with higher initial values of the vitality function, suggesting that exceptional survival was likely to have a genetic background. The more longevity alleles that were carried by study participants the higher was the value of their initial stress resistance. In terms of genetic functions, the resistance to stresses is associated with repair capacity, redundancy, and other functions that increase an organisms' resilience, or robustness. A useful illustration of how increased resilience may influence survival can be given by using the model of saving lives (Vaupel and Yashin, 1987). An increase in the 'number of lives being saved' for individuals in the population can be interpreted as an increase in redundancy: for each lost life (premature death), the decedent has one or more 'redundant' lives, depending on the relevant advances in medical technology.

Stochastic Process Model

Strehler and Mildvan's (1960) theory stimulated further research in the direction of biodemographic analysis of mortality rates. Woodbury and Manton (1977) introduced a multivariate stochastic process model of human mortality and aging. This model has been intensively used in analyses of longitudinal data on aging, health, and longevity (Manton et al., 1995). This model was further extended in Yashin et al. (2011) to incorporate state of the art advances in aging research into the model structure. In particular, the extended model described partly observed aging-related changes in physiological variables linked together with age-dependent unobserved variables that included resistance to stresses, adaptive capacities, physiological norms ('optimal' physiological states), stochasticity, allostatic adaptations, and allostatic load. Together, these extensions represented biological mechanisms of aging-related changes in humans, which were consistent with existing biological knowledge about aging. The model described how the age-dependent unobserved variables interacted with partly observed physiological indices and other factors, and linked them with health and survival outcomes. This provided a convenient conceptual framework for comprehensive systemic analysis of aging-related changes in humans using longitudinal data and for linking these changes with genotypic profiles, and morbidity and mortality risks. The model has been used to develop unique efficient statistical methods for analyzing longitudinal data on aging, health, and longevity.

Fertility–Mortality Trade-Off

It has been argued that the priority that natural selection places on reproduction negatively affects other processes such as longevity; the problem posed by this trade-off underlies the disposable soma theory for the evolution of human aging (Drenos and Kirkwood, 2005). The innate immunity could be a critical factor skewing an individual into the direction of either a high fertility or better maintenance strategy (Van Bodegom et al., 2007). Over thousands of years, resistance to infectious diseases through inflammatory host responses was favored because it allowed humans to survive up to reproductive age. Such responses, however, may be negatively associated with fertility and may explain the trade-offs between fertility and the subsequent development of chronic degenerative diseases. The data on historical human populations do not support the hypothesized negative effects of reproduction on longevity: married women who remained childless lived no longer than women who reproduced and women who had few children lived no longer than women who had many children (Lycett et al., 2000). However, the relationship between longevity and reproduction gets stronger with increasing poverty. Other data show a negative influence of parity and a positive influence of age at last childbirth on postreproductive survival, as well as a significant interaction between these two variables (Gagnon et al., 2009).

Index of Cumulative Deficits (DI)

Index of cumulative deficits (DI) or frailty index appears to have broad utility as a promising measure of systemic aspects of aging. The properties of the DI have been validated using various data sets, including the National Long Term Care Survey, the National Health and Nutrition Examination Survey, the Canadian Study of Health and Aging, the Australian Longitudinal Study of Aging, and others. The DI predicts mortality outcomes (Mitnitski et al., 2001; Kulminski et al., 2007) and it does so better than chronological age does. This index is associated with morbidity, activity of daily living (ADL) limitations, cognitive impairment, institutionalization, and hospitalization. The DI has similar relationships with age regardless of the nature of the specific deficits, so long as the set of deficits is reasonably broad; moreover, these relationships hold across a range of settings. The DI was found to reach maximum levels that were age independent, which suggests that there is a limit to the extent of deficit accumulation that is compatible with life. It has the potential to describe biological aging and differentiate short- and long-life phenotypes. In addition, an important aspect of the DI is that it allows one to more comprehensively address the health/well-being of an individual by representing mild-effect traits (i.e., traits which are traditionally ignored in analyses due to their low individual effects) in a coherent way. Since the DI includes dimensions that are readily available from typical population-based studies, it appears to be a promising candidate to serve as a measure of

aging that could be used in demographic models. Thus, on the one hand, the DI can summarize a range of measures relevant to the biology of aging that are amendable to preventive interventions and, on the other hand, it can be incorporated into individualized and/or population-based models of senescence, longevity, and mortality. To find the best descriptions of aging-related declines in health/well-being, further mathematical modeling and comparative analyses of different indices are needed.

The future

The future of this research area depends on the progress in understanding factors and biological mechanisms involved in regulation of aging, and their connections to mortality. These include progress in experimental fields and advances in understanding evolutionary forces shaping age patterns of mortality (*see* Evolutionary Demography: A Synthesis of two Population Sciences).

Mortality Crossover

Irma T Elo, Population Studies Center, University of Pennsylvania, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Mortality crossovers refer to a phenomenon where one population or population subgroup has higher age-specific death rates at younger ages but lower age-specific death rates at older ages than a comparison population or population subgroup. Mortality crossovers have been documented in the United States between whites, African-Americans, Hispanics and Native Americans, and among developed and developing countries. Such mortality crossovers are attributed to mortality selection and population heterogeneity or to age misreporting at advanced ages.

A mortality crossover is said to occur when mortality curves of two populations or population subgroups intersect. At younger ages, age-specific death rates for one population exceed those of the other, with a gradual narrowing of differentials as age advances, until at some older age the death rate differentials are reversed. Such intersection of mortality curves has provided empirical support for theories of mortality selection and 'the survival of the fittest' mechanism in old age mortality. Others have argued that the observed mortality crossovers are simply a consequence of age misreporting.

Empirical Evidence

One of the most widely noted mortality crossovers is that observed for African-Americans and whites in the United States. Throughout the twentieth century, mortality estimates based on vital statistics and census data have consistently shown black death rates to exceed white rates until some age above the mid-70s at which point white rates exceed black age-specific death rates. The greatest relative disadvantage for African-Americans is observed in middle age, and the age at which the two rates cross has increased over time (Pearl, 1922; Lynch et al., 2003). Investigations of black–white mortality differentials by cause of death have also revealed a crossover in cause-specific death rates, although the relative differentials by age vary substantially by cause of death, with mortality crossovers observed for some but not for all causes of death (Eberstein et al., 2014; Hussey and Elo, 1997; Elo and Preston, 1997; Manton et al., 1979; Manton and Stallard, 1997).

Evidence from linked data sources, where information for deaths and population at risk comes from a single source, also shows a black–white mortality crossover at the oldest ages. Kestenbaum (1992) has conducted a careful analysis of mortality based on Medicare and Social Security data for black and white Americans at ages 85 and above. Black mortality exceeded or was the same as white mortality up to age 87 for males and up to age 88 for females, at which ages the rates crossed over. Similarly, mortality estimates based on the National Longitudinal Mortality Study, the National Health Interview Survey linked to the National Death Index, the American Changing Lives study, and small-scale, longitudinal data sources show a crossover in black and white death rates at the oldest ages (Dupre et al., 2006; Eberstein et al., 2014; Elo and Preston, 1997; Masters, 2012; Sautter et al., 2012; Yao and Robert, 2011).

A mortality crossover is also observed for Hispanics and non-Hispanic whites and Native Americans and whites in the United States, but at a younger age than for blacks and whites (Elo and Preston, 1997; Thornton, 2004). For example, Hispanic Americans have higher mortality than non-Hispanic whites at younger ages and lower mortality after about age 40–45 with the proportionate gap between Hispanic and white rates increasing with age. At least some of the Hispanic advantage appears to be due to the exceptionally low mortality of the foreign-born. Hispanic populations in Latin America are also known for having unusually low death rates at older ages relative to their level of mortality at younger ages (Elo and Preston, 1997; Dechter and Preston, 1991).

Empirically observed mortality crossovers are not limited to the United States. Coale and Kisker (1986) compared death rates in selected life tables for developed and developing countries with a similar life expectancy at age five. In each pair of life tables considered, death rates at younger ages in the developing country exceeded those of the developed country, while at the oldest ages the relative differentials were reversed. Nam et al. (1978) investigated mortality crossovers by comparing life table death rates for pairs of national populations where one population was considered low and the other high income. Of the 1035 pairs of mortality curves examined, for 16% of the original pairs the authors' findings were consistent with the hypothesis that the more disadvantaged lower income populations would have higher mortality at younger ages but lower mortality at older ages.

Manton and Vaupel (1995) also documented a crossover in death rates at the very oldest ages between white Americans and populations in England, France, Sweden, and Japan. In Japan and the European countries, life expectancy at birth was notably higher than in the United States. Death rates, however, began to converge around age 65, and above age 80 the U.S. rates fell below those of the European countries and Japan. More recently, Ho and Preston (2010) similarly showed that although U.S. male and female age-specific death rates in 2005 were among the highest among 17 OECD countries between ages 40 and 70 for males and 40 and 75 for females, at older ages the U.S. death rates rose less sharply than in most comparison countries and above age 90 the U.S. death rates were among the lowest.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31045-5

Proposed Explanations

Most observers attribute mortality crossovers either to selective survival and population heterogeneity or to poor data quality at the oldest ages.

Selective Survival and Population Heterogeneity

Manton and Vaupel have been in the forefront of advancing theories involving selective survival and population heterogeneity (Vaupel et al., 1979; Manton and Stallard, 1981; Manton et al., 1979). In a heterogeneous population, where individuals have different susceptibilities to mortality that are fixed at birth, frailer members of a cohort die at younger ages leaving a more robust group of survivors at successively older ages. If we further consider two population subgroups that have the same distribution of frailty, but one is subject to more adverse conditions in early life then its frailest members are eliminated more quickly than among the advantaged group. If such selection is appropriately balanced, it is theoretically possible that a crossover of the mortality curves for the two population subgroups is observed at some advanced age (Manton et al., 1979; Olshansky, 1995).

Although the above mechanism is feasible, it requires that genetic endowments for longevity are fixed at birth and remain constant over the life span. However, life style and environmental factors are likely to influence individual as well as population longevity. To address this possibility, Manton and his colleagues have extended the selection hypothesis to acknowledge the potential impact of environmental factors on differential rates of population aging (Manton et al., 1979). It has been further shown that mortality crossovers between two populations can occur even when the age pattern of mortality is the same for all individuals, but the distribution of frailty varies among them. Mortality will rise less rapidly with age in a population with a greater degree of heterogeneity at the same mean level of frailty (Vaupel, 2010 cited in Ho and Preston, 2010).

The crossover in black and white death rates at older ages has provided much of the empirical support for the mortality selection and survival of the fittest explanations. Given large socioeconomic differentials between whites and blacks and the adverse conditions African-Americans experienced earlier this century, it is conceivable that selective survival has been more pronounced for blacks than for whites. Evidence from other populations, however, suggests that cohorts who experienced unfavorable conditions in early life also tend to experience elevated mortality at older ages (Elo and Preston, 1992; Finch and Crimmins, 2005; Janssen et al., 2005). A handful of studies have used individual and/or neighborhood level socioeconomic conditions and religious attendance as sources of population heterogeneity to examine whether these sources of heterogeneity can help explain the black–white mortality crossover with mixed results (e.g., Dupre et al., 2006; Sautter et al., 2012; Yao and Robert, 2012). A recent study by Masters (2012) in turn points to a potentially important role of black–white differences in cohort patterns of mortality in the black–white mortality crossover. Using hierarchical age-period cohort methods, the author finds that non-Hispanic black and non-Hispanic white age-specific mortality rates do not crossover at any age, controlling for period and cohort patterns of adult mortality.

Selective survival and population heterogeneity have also been invoked as a possible explanation for the low mortality in the United States relative to other OECD countries at the oldest ages. Other potential explanations for this pattern include cohort differences in education, immigration, access to health care, and health behaviors as well as more extensive medical interventions in the United States than in other OECD countries at the oldest ages (Manton and Vaupel, 1995; Ho and Preston, 2010).

Poor Quality Data and Age Misreporting

The second explanation for mortality crossovers is that they are produced by poor data quality. It is hypothesized that age misreporting in death statistics and/or censuses biases mortality estimates downward at the oldest ages. Age overstatement has been considered the most common form of age misreporting, although other patterns have also been recorded (Ewbank, 1981; Preston et al., 1999). Preston et al. (1999) have further shown that various patterns of age misreporting – net age overstatement, net age understatement, and symmetric age misreporting – bias mortality estimates downward at the oldest ages. The downward bias is produced by all methods of mortality estimation the authors considered: conventional methods derived from vital statistics and censuses; longitudinal studies where age is identified at baseline; variable-*r* procedures based on age distribution of the population; variable-*r* procedures based on age distribution of deaths; and extinct generation methods. Thus, it is not unreasonable to propose that age misreporting at the oldest ages has led to downwardly biased death rates at the oldest ages and spurious mortality crossovers.

In their study of life tables for developed and developing countries, Coale and Kisker (1986) concluded that the mortality crossovers they observed were caused by poor data quality. Age misreporting has also been implicated in the low mortality of Hispanics at the older ages relative to the U.S. white population. Other potential explanations for the low mortality of Hispanics include the positive selection of migrants on such characteristics as healthiness, difficulty of following the foreign-born in U.S. death records, and return migration to countries of origin by those in poor health, i.e., the salmon bias hypothesis (Abraido-Lanza et al., 1999; Elo and Preston, 1997). The lower mortality of Hispanics compared to the non-Hispanic whites, however, has been observed not only in vital statistics and census data but also in Social Security and Medicare data where age misreporting is less likely to be present (Elo et al., 2004). Turra and Elo (2008) have further shown that although salmon bias is likely to play a role in the Hispanic mortality advantage at the older ages, it is too small in magnitude to be a primary explanation for the lower mortality of Hispanics than non-Hispanic whites in the United States at ages 65 and above.

The most extensive studies of the potential impact of age misreporting on mortality crossovers pertain to the black–white mortality crossover in the Unites States. There is a general agreement that age misreporting has seriously biased African-American death rates downward at the oldest ages. The first study to document inconsistencies in age reporting for

African-Americans and whites in vital statistics and census data was the 1960 Matched Records Study, which linked death certificates registered in May to August in 1960 to the 1960 Census of Population. For less than half of the nonwhite male and female matched cases was the age in the two sources identical. Age reporting was far better for whites. After the data were corrected for age misreporting, the racial crossover in mortality moved from the age interval 75–79 to the last open-ended age interval, 85 and older (Kitagawa and Hauser, 1973).

Two recent matched-record studies of death certificates from the 1980s for whites and African-Americans to early census records for these same individuals when they were children or adolescents continue to show substantial age misreporting for African-Americans in death statistics at the oldest ages, but minimal problems for whites. Thus, conventionally constructed death rates from vital statistics and census data for African-Americans continue to be understated at the oldest ages. In contrast, death rates for whites do not show a systematic bias. A comparison of mortality rates for blacks and whites based on corrected data continues to reveal a mortality crossover for males in the age interval 95+ and for females at ages 90–94 (Preston et al., 1996; Hill et al., 2000). Age-specific death rates for this comparison were, however, based on somewhat unconventional variable-*r* procedures and on a very small number of deaths for African-Americans at the oldest ages. Lynch et al. (2003) also found that the age of black–white mortality crossover was at a later age when estimates were based on data adjusted for possible age misreporting than on unadjusted data. The affirmation of the reliability of mortality estimates for whites lends support to the findings by Manton and Vaupel (1995) and Ho and Preston (2010) that white mortality in the United States at the oldest ages is lower than in most OECD countries.

The above findings raise compelling questions about the possible underlying factors for various observed mortality crossovers. It is unlikely that a single explanation will account for them or for the convergence of death rates at the oldest ages under all circumstances. To gain greater insights into the variability in the aging process, it is important to explain not only those instances where crossovers occur, but also when they have failed to materialize.

Mortality Differentials: Selection and Causation

Noreen Goldman, Princeton University, Princeton, NJ, USA

Abstract

Differentials in mortality by socioeconomic status and the nature of social relationships have been well established in a broad range of settings and time periods. A myriad of studies has investigated the many potential causal pathways linking these aspects of the social environment to health and mortality, with a current emphasis on psychosocial factors, neighborhood contexts, and biological linkages. Recent efforts have exploited longitudinal surveys, some beginning at birth, to strengthen causal inferences. Fewer researchers have focused on identifying selection mechanisms or reverse causal pathways through which, for example, poor health may lead to reduced income or exclusion from marriage.

Differentials in mortality by socioeconomic status (SES) and the nature of social relationships have been well established. In general, persons of higher SES (e.g., those with higher income, education, and occupational class) and persons who are more socially integrated (e.g., those who are married) experience lower death rates than their respective counterparts. These associations have been found across time and place – including industrialized and developing countries – although with some exceptions. Three sets of hypotheses have been proposed by researchers to explain these patterns. The first encompasses *causal* mechanisms through which SES and social relationships potentially affect health status and the risk of dying. A second type of explanation, referred to as *selection* or *reverse causation*, pertains to a set of pathways whereby unhealthy individuals may reduce their SES or become less socially connected as a consequence of their inferior health status. A third explanation relates to *artifactual* or *spurious* mechanisms, such as measurement error.

SES and Mortality

Differences in rates of morbidity and mortality by SES have been identified for the vast majority of illnesses, along a social gradient: persons of higher SES fare better than those lower in the social hierarchy (Adler et al., 1993). These differences typically (1) are present regardless of whether SES is defined in terms of income, wealth, education, or occupation; (2) exist throughout the social hierarchy (i.e., not simply between the poor and the nonpoor); and (3) have been documented in a large number of studies in both industrialized and developing countries, based on vital registration, census, and survey data. There are exceptions, however. For example, there is no clear mortality gradient among older adults in Costa Rica (Rosero-Bixby and Dow, 2009) and some Hispanic groups in the US have relatively shallow gradients in health and mortality (Goldman et al., 2006; Turra and Goldman, 2007).

Many of the studies examining the link between SES and health have been based in Western populations, especially the United States and Britain. Two long-term investigations in Britain have been used extensively to examine social differentials in health. One is the Whitehall Study, which tracked a sample of British civil servants since 1967 (Whitehall I) and another sample since 1985 (Whitehall II) (Marmot et al., 1995; Marmot and Brunner, 2005). The original Whitehall study is frequently credited with establishing the existence of a gradient in health – e.g., the study demonstrated that mortality differentials are present throughout successive grades of employment even within a relatively homogeneous group: civil servants in stable office jobs in London. Whitehall II has the explicit mission of examining social gradients in health and illness. A second set of frequently analyzed data comprises four large national birth cohort studies: three that have been following births that occurred in England, Scotland, and Wales during 1-week periods in 1946, 1958, and 1970 and a fourth (the Millennium Cohort Study) that has been following births in the 2000–01 period.

Many recent investigations have focused on assessing the extent to which causal rather than selective or spurious mechanisms drive the observed socioeconomic inequalities in health. To reduce the impact of bias in the statistical analysis, researchers have relied largely on prospective (longitudinal) data, such as those described above. Although many of these studies provide some control for selection-type biases, relatively few studies study such biases explicitly. There is a general consensus among epidemiologists and health researchers that the observed disparities in health are not driven by *social selection*, also referred to as *social drift*, or *reverse causality*. Specifically, while there is some downward drift in SES among persons in poor health (e.g., schizophrenics may lose income or their jobs because of their health), many health researchers argue that this type of mechanism is unlikely to be an important part of the association between SES and a wide range of health indicators (see, for example, Davey Smith et al., 1994; Marmot et al., 1995; Macintyre, 1997).

In contrast, economists typically recognize the potential importance of reverse causality. For example, Smith (2004) uses data from national longitudinal surveys in the US (the Health and Retirement Study and the Panel Study of Income Dynamics) to examine the impact of new serious health events among older adults and concludes that such health shocks have a substantial impact on work, income, and wealth. In a study examining the link between children's health and social mobility, Case and Paxson (2006) demonstrate that health problems during childhood can affect economic success in adulthood, partly through poor educational achievement.

Various studies – particularly those examining reverse causal processes – underscore the importance of distinguishing among the different components of SES when examining linkages with health – e.g., among adults, poor health may reduce income and wealth but it is unlikely to impact years of schooling. The effects of poor health on social status are also likely to vary by the nature of the illness or condition, with stronger associations apparent for some mental illnesses and severely disabling diseases. For example, schizophrenia and epilepsy have been linked to the reduced social mobility (Goldberg and Morrison, 1963; Harrison and Taylor, 1976).

It is also possible that the associations between SES and health arise, at least in part, from *indirect selection* mechanisms, i.e., background (or *spurious*) factors, such as height, genetic characteristics, parental behavior, and self-efficacy, that affect both health status and social mobility. Unfortunately, many of these factors are difficult to measure and some are themselves the result of social status. Artifactual mechanisms (e.g., errors of measurement, such as census undercounts, 'numerator–denominator' problems, such as inconsistencies in reports between registration and census data, or inappropriate measures of mortality or SES) provide another possible explanation of the observed associations. However, increasing reliance on longitudinal surveys rather than cross-sectional data has reduced concerns about most of these methodological issues.

The strong belief in the causal linkages between socioeconomic position and health has led some social science and health researchers to view SES as a 'fundamental cause' of disease (Link and Phelan, 1995). The underlying idea is that social inequalities in health have persisted across time and place, despite radical shifts in the disease environment, risk factors of disease, and technology, because SES always entails access to resources that affect exposure to disease, maintenance of health, and treatment of illness. Because of the endurance of these health inequalities, Link and Phelan (1995) discourage research that focuses on the 'proximate determinants' of illness – i.e., the specific mechanisms that link social position to health or illness. Nevertheless, in an effort to gain a deeper understanding of social inequalities in health, many studies seek to identify the particular causal mechanisms that relate differences in SES to differentials in health and mortality. Possible pathways include differences in (1) access to medical care, both preventive and curative; (2) access to information regarding health risks and health care; (3) patterns of health risk behaviors (such as smoking, drinking, unhealthy diet, and inadequate exercise); (4) exposure to environments that are not conducive to good health and longevity (e.g., poor housing conditions, occupational hazards, pollution, and crime); (5) exposure to stressful situations; (6) access to resources that mediate the physiological consequences of stress; (7) ability to control one's environment and feel secure about one's position; and (8) the availability of social relationships and support.

Researchers who have focused on a single mechanism have concluded that *multiple* causal pathways almost certainly underlie the observed associations. For example, although the higher death rates experienced by persons of lower SES in several British and American studies have been shown to result in part from higher rates of smoking, poorer diets, and inadequate levels of exercise, these differences in behavior were insufficient to account for the observed mortality differentials (Marmot et al., 1995; Macintyre, 1997). Similarly, the widening of mortality differentials by SES between the 1960s and 1980s in Britain and the US – despite the presence of the National Health Service in the former and Medicaid in the latter – has been taken as evidence that the explanation goes beyond inequities in access to medical care (Davey Smith et al., 1990; Pappas et al., 1993). More recent studies demonstrate a continued widening of social inequalities in health in the US and Europe (Mackenbach et al., 2003; Marmot, 2003; Singh and Siahpush, 2006), but reasons for this temporal pattern are not well understood.

In recent years, researchers have broadened the theoretical framework underlying the study of mortality differentials, devoting increasing attention to the following types of factors causally linking social status to health: (1) psychosocial influences; (2) neighborhood context; and (3) biological pathways (Chen and Miller, 2013). For example, studies have examined how different occupations or social positions vary with regard to stressful experiences, anxiety, mastery, depression, discrimination, and the ability of individuals to control their lives (Marmot, 1999). Other research has focused on individuals' broader social environment, considering, for example, racial and ethnic composition, neighborhood violence, and neighborhood social capital. Some researchers have argued that an individual's health is related not only to his or her absolute income or family income, but also to the level of income inequality in the society, with higher degrees of inequality associated with poorer health and survival (Wilkinson, 1996), However, the evidence relating societal income inequality to population health is plagued by methodological issues and poor data quality and is inconclusive (Subramanian and Kawachi, 2004; Lynch et al., 2004). Another advance has been the incorporation of physiological measurements, often referred to as biomarkers, into social science surveys. These new data collection efforts have allowed individuals to begin to elucidate the biological mechanisms that underlie social disparities in health and mortality, considering standard clinical factors (such as blood pressure, cholesterol levels, or blood glucose levels), markers of inflammation and immune function, and neuroendocrine mechanisms (Karlamangla et al., 2012; Turra et al., 2005). Researchers often describe such efforts as 'getting under the skin' of social disparities in health. Biomarkers have also been used to explore the potential role of exposure to chronic stressful experience – via increased 'allostatic load' – in mediating the relationship between SES and health (McEwen, 1998).

Most research linking SES to health relies on what epidemiologists refer to as observational studies. As noted above, the most useful of these studies have been prospective surveys that collect extensive information on the social environment, health, and survival. These data generally allow the analyst to measure preexisting conditions that may confound the association between SES and health, to relate changes in SES to subsequent changes in health, and to control for potentially confounding variables. Given increasing recognition of the influences of social factors on health throughout the life cycle, prospective surveys that begin early in life are especially useful. A myriad of studies has established that early life experiences related to the socioeconomic position of the family – e.g., family composition, parent–child interactions, the presence of

child abuse – can have wide-ranging effects on physical and mental well-being in adulthood (see, for example, Wadsworth and Kuh, 1997; Power and Hertzman, 1999; Elo, 2009). Influences on adult health can begin as early as birth or even the prenatal period (Barker, 1999). Studies of children have demonstrated steeper gradients with the age of the children, suggesting, for example, stronger impacts of family income on children's health as the children grow (Case et al., 2002). Studies have also demonstrated that the magnitude of social disparities in health and survival generally declines at the older ages, due, at least in part, to heterogeneity in the risk of dying by social status (Zajacova et al., 2009).

Despite the richness of prospective surveys, there are of course many impediments to causal inference from observational studies, including confounding, omitted variable bias, and endogeneity. Although experiments – i.e., randomized, controlled, double-blind trials – are the gold standard for causal inference in medicine and epidemiology, they are generally not feasible or ethical, and often not very informative in the social sciences since investigators are constrained by the types of social conditions that can be manipulated. Nevertheless, there have been experiments, quasi-experiments (which do not entail randomization but involve researchers' control over the intervention), and natural experiments (in which treatment allocation is not under researchers' control but seems to be haphazard or close to random) in this field of study. For example, using findings from an experimental demonstration project known as Moving to Opportunity, researchers examined the impact of randomly assigned housing vouchers, which allowed residents of public housing to move to lower poverty areas, on obesity and diabetes (Ludwig et al., 2011). In an intervention in which exposure to illness (by inhalation of the virus), rather than social position, was assigned by the investigators, Cohen and colleagues (Cohen et al., 2008) analyzed the association between SES and development of viral infection. Economists have used natural experiments to identify causal impacts of SES on health by examining whether changes in health follow an external change in policy (e.g., compulsory schooling; Lleras-Muney, 2005). Other studies have considered the impact on health of such seemingly exogenous events as the reunification of Germany, increased income from casinos among American Indians, and winning a lottery (Evans et al., 2012). Some quasi-experimental studies that examine links between social position and health involve animals, particularly nonhuman primates. For example, Shively and colleagues manipulated the relative social status (dominant vs subordinate position) of monkeys and assessed the subsequent development of atherosclerosis (Shively and Clarkson, 1994). Despite their usefulness at reducing the threats to causal inference that characterize observational studies, these experimental-type investigations – whether on animals or humans – cannot examine the complex set of interrelated pathways, with multiple moderating influences, that operate in actual social environments to impact human health (Goldman, 2001).

Social Relationships and Mortality

A related area of research has examined the associations between *social relationships* and health and mortality. These undertakings have concluded that persons who are less socially integrated have higher rates of illness and lower life expectancy than their counterparts. The associations are present for a wide range of causes of death. The possible interpretations of these findings mirror those described above, namely causal vs selection-type arguments. Causal explanations encompass a broad set of pathways through which the availability of social connections or social support can, for example, protect persons from health risks and unhealthy behaviors (e.g., smoking and poor diets), provide access to health-related information, increase individuals' sense of control and self-esteem, and buffer responses to stressful experiences. Selection-type arguments posit that people suffering from mental or physical illnesses are less likely to establish and/or maintain social relationships or that some other variables reduce a person's ability to have positive relationships and maintain good health.

As with studies of SES, prospective studies have provided much more convincing evidence than cross-sectional or retrospective ones regarding the importance of causal mechanisms in producing the association between social relationships and health. For example, a set of prospective community studies carried out in the 1970s and 1980s demonstrated that levels of social integration – a measure comprised of various indicators of social ties and activities – were positively and strongly associated with survival among adults (House et al., 1988). In a recent meta-analysis based on 148 studies involving more than 300 000 individuals followed for an average of 7.5 years, Holt-Lundstad and colleagues concluded that persons with adequate social relationships had a 50% greater probability of surviving than those with inadequate relationships. They argued that this magnitude of effect surpassed that for many well-known mortality risks, including obesity and lack of physical activity (Holt-Lunstad et al., 2010).

Findings from surveys have been strengthened by experimental and clinical research, which has demonstrated that variations in the degree of social contact have psychological and physiological effects in animals and humans (House et al., 1988). For example, partly by reducing individuals' negative appraisal of stressful experiences, social relationships are thought to improve cardiovascular and immune functioning (Uchino et al., 1999). Similarly, Cacioppo and colleagues have shown that loneliness – in particular, subjective feelings of loneliness – impacts the sympathetic nervous system, the immune system, and the brain (Miller, 2011). A large number of studies have demonstrated that even simple interventions – such as the presence or petting of companion animals – can improve the physical and mental well-being of adults (Wells, 2011).

While the availability of social ties and support provided by these individuals is generally thought to have a positive influence on well-being, not all relationships are beneficial. For example, through a series of experimental-type studies, researchers have demonstrated that married couples experiencing conflict and hostile behavior experienced dysregulation in cardiovascular and immune function (Robles and Kiecolt-Glaser, 2003).

Marital Status and Mortality

Marriage is often considered one of the strongest sources of social support. The earliest research on social connection and

health – dating as far back as the mid-1800s – focused largely on marital status. Since that time, hundreds of studies, primarily in industrialized countries, have demonstrated that married persons have greater longevity and experience better health than single, divorced, and widowed persons. These results generally hold across time and place. In most studies, differentials in mortality by marital status have been larger for men than for women, although a recent meta-analysis found no sex difference in the magnitude of the effects for the older population (Manzoli et al., 2007). The relative rankings of the different unmarried states in terms of mortality risk vary across studies, but Rendall and colleagues argue that many claims of differences across the unmarried groups are not supported by statistical tests; they demonstrate that, in a large US study, there is little evidence of survival differences among single, widowed, and divorced/separated persons (Rendall et al., 2011). As with the broader field of social disparities in health, studies of marital status differentials in mortality are relying increasingly on prospective rather than cross-sectional data.

Once again, the dominant hypotheses for the better survival profile of married persons comprise causal vs reverse causal/selection explanations. Causal hypotheses, often termed *marriage protection* in this literature, encompass a broad range of social, psychological, economic, and environmental benefits that are presumed to be associated with having a spouse. Many of these are similar to the mechanisms described above hypothesized to link social connection to health and survival. For example, the presence of a spouse is hypothesized to (1) result in greater emotional and social support; (2) lead to higher income; (3) facilitate access to medical information and health services; (4) constrain risk-taking behavior and encourage healthier lifestyles; (5) act as a buffering mechanism in the presence of stress; and (6) substitute for inferior or inaccessible formal health care. Moreover, the termination of marriage – either by divorce or death of a spouse – is believed to lead to higher risks of dying because of the stresses associated with the loss of a spouse (e.g., *bereavement effects* in the case of widowhood) and the accompanying decline in social and economic resources. However, as suggested earlier, differences across the marital states in terms of health impacts are not always clear-cut: marriage can lead to spousal conflict, which has a negative impact on health; in such cases, divorce may have a more positive impact on health than an unhappy marriage.

The health consequences of being unmarried are likely to vary across societies as a function of social and cultural factors. For example, in societies where marriage is an integral part of one's social status, and is virtually universal, persons (especially women) who remain single or get divorced are likely to face discrimination and the concomitant negative consequences for their health.

Marriage selection arguments, by contrast, are based on the premise that mentally and physically healthier persons are more likely to marry in the first place, less likely to become widowed or divorced, and more likely to remarry if a previous marriage dissolves. The factors that drive the selection criteria may be far from obvious. For example, spouses may be selected for better health not only through the direct exclusion of mentally and physically ill persons from first marriage or remarriage, but also through a range of criteria that govern mate selection (i.e., *indirect selection*) such as income, physical appearance (e.g., height, weight, and beauty), health-related habits (e.g., smoking and drinking), and emotional stability.

In line with studies of SES and social connection, analyses focusing on marital status have typically concluded that the associations with mortality are produced predominantly by various benefits associated with having a spouse and not by marital selection. While this conclusion may generally be correct, many of the inferences drawn by researchers have not been justifiable. In addition, selection appears to be the dominant source of the observed differentials in at least one population (described below).

Two types of problems of inference have been noted. The first is that, in the past, demographers often based their arguments on cross-sectional data. In particular, some demographers have reached conclusions about the importance of marital selection on the basis of aggregate patterns of mortality by marital status, e.g., age patterns of mortality differentials and the direction and strength of the relationship between the magnitude of the mortality differential and the relative size of the single population. Results from a simple simulation model demonstrate that the resulting inferences are not justifiable because both causal and selection processes could lead to the same aggregate patterns of mortality (Goldman, 1993a).

The second type of weakness pertains to unjustifiable inferences derived from prospective data. Although these data have permitted researchers to conclude that the health benefits of marriage (or of higher SES) persist in the presence of controls for selection, they have also led some to argue that selection mechanisms are unimportant. The latter conclusion has generally been unwarranted: existing statistical analyses frequently include controls for selection processes, but most were not designed to *measure the impact* of selection. More recently, some demographers have analyzed longitudinal data in an effort to directly assess health-related selection into first marriage and into divorce. These studies have demonstrated that health-related characteristics and behaviors are used (explicitly or implicitly) as selection criteria for marriage and divorce. For example, in the US, users of illicit drugs, heavy drinkers, and obese persons have lower marriage rates than their respective counterparts (Fu and Goldman, 1996).

Perhaps because demographers (like other social scientists) have been most interested in identifying causal mechanisms, they have often failed to recognize that the impact of selection on mortality differentials by marital status is likely to vary across societies. A study of atypically high mortality among never-married Japanese demonstrates this point clearly. As of the mid-1900s, a 20-year-old never-married Japanese man or woman could expect to live about 15 years less than his or her married counterpart. Data from a variety of sources strongly suggest that the Japanese arranged marriage process appears to be largely responsible for this huge discrepancy in longevity. Several characteristics of arranged marriages are particularly noteworthy in this context: the importance of mental and physical health, particularly conditions thought to be genetically determined, in the choice of a potential spouse; the inclusion of family, friends, go-betweens, and even private detectives in the selection of a mate; and, the efficiency of the mate selection process (Goldman, 1993b). As arranged marriages were replaced by love marriages during the second

half of the twentieth century, the relative mortality rates of never-married Japanese progressively diminished.

Future Directions

Despite extensive research focusing on mortality differentials by SES and by the nature of social relationships, much remains unknown about the relative importance of different causal and noncausal pathways in producing the associations. Two current trends in data collection are likely to increase scientists' understanding of these linkages in the future. The first is the increasing breadth of longitudinal surveys in the social sciences. Some surveys, which follow individuals from the time of birth, are able to capture critical early life influences on subsequent social status and health; with increasing lengths of follow-up, these surveys have amassed information for a substantial part of the life cycle. Using such rich survey data, analysts have been able to take a life course perspective to examine the antecedents and consequences of poor health; explore multilevel influences on health that comprise individual, family, and community-level variables; and identify salient moderators of the links between low SES and poor health. The second innovation is the noninvasive collection of biological and clinical markers as part of social science surveys. By identifying some of the physiological pathways relating aspects of the social environment to physiological outcomes, such as neuroendocrine response, immune function, and cardiovascular function, social scientists may gain additional insights into the causal linkages that underlie the observed mortality differentials. The number of biosocial surveys has increased dramatically in recent years and is likely to continue to do so in the near future.

Abstract

In demography, mortality transition marked the shift from higher to lower mortality rates. In the medical epidemiological field, the analyses of the mortality trend by cause of death led to the formulation of the theory of epidemiological transition, used to mark the shift from a phase when infectious diseases were the primary cause of death, to one in which chronic diseases were the chief cause. Since the 1970s, the concept of epidemiological transition has taken on a new significance that is also more far-reaching and thorough. The stance taken to analyze structural changes in mortality by age and cause has changed: it is no longer merely descriptive but now also tries to define the link with the triggering determinants, including the wider concept of health transition.

Theoretical Concept of Mortality, Epidemiological, and Health Transitions

The study of changing trends in mortality which affect Europe together with certain non-European societies with deep European roots (the United States, Canada, Australia, New Zealand, Argentina, and Uruguay) has led to the theory of 'demographic transition,' a term coined to designate the historical process which marked the shift from an older mortality and fertility regime to a new one. In particular, the process of 'mortality transition' marked the shift from higher rates (over 30 per 1000) to lower rates (10–12 per 1000). This process of change in mortality in European countries has for a considerable time engaged the attention of academics in various fields: demographers as well as economists, medical researchers, epidemiologists, and geneticists among them. There is still considerable discussion about the underlying reasons for the decline of mortality (particularly during the eighteenth century), and many different views have been put forward (Livi Bacci, 1987; McKeown and Brown, 1955; McKeown and Record, 1962; McKeown, 1976; Wrigley and Schofield, 1981). It could hardly be otherwise, when mortality decline has been studied by means of a single global indicator (growth mortality rates). It has seldom been possible to study changes in sex- and age-specific mortality, and rarer still to consider changes to mortality by causes of death before the end of the nineteenth century. However, it is only by looking at changes in causes of death that we shall be able to identify the determinants which have resulted in falling mortality. In the nineteenth and twentieth centuries, the indicators of mortality by age and cause of death have helped demographers to a better understanding of the long mortality transition process.

In the medical epidemiological field, the analyses of the mortality trend by cause of death led to the formulation of the theory of 'epidemiological transition' (Omran, 1971), used for many years to mark the shift from a phase when mortality levels were high, with infectious diseases as the primary cause, to one in which mortality levels had notably declined, with chronic diseases being the chief cause. In the 1970s, the concept of epidemiological transition had taken on a new significance that is also more far-reaching and thorough. The stance taken to analyze structural changes in mortality by age and cause had changed; it was no longer merely descriptive but now tried also to define the link with the triggering determinants. From this viewpoint, moving from description to an explanation of the changes in the diverse mortality profile, the definition 'epidemiological transition' gave way to 'health transition' (Lerner, 1973). In the 1970s, the spectacular decline in mortality from cardiovascular disease that could be seen in all Western countries called into question the very concept of epidemiological transition, which was centered on the development of pathologies. In fact, in the 1990s, John Caldwell (1990), Graziella Caselli (1989, 1991, 1996), and Julio Frenk et al. (1991) proposed replacing the concept of epidemiological transition with the broader one of health transition, incorporating in the description of the development of mortality both the development of the epidemiological characteristics of the health situation and those of society's response to this state of health.

In what follows we shall analyze the historical development of the decline of mortality, following the various stages of the transition process in relation to the role played by changes in the epidemiological framework and the determinants that have produced them.

From Mortality Crises to the Mortality Transition

At the outset of the eighteenth century, man had not yet succeeded in mastering the forces of nature, and life expectancy, which was short even in normal times, was affected by subsistence crises and famines that resulted in misery and extremely high death rates. The effects of these crises were often made worse by epidemics of plague and other fevers (Caselli, 1989, 1991).

Of these various crises, which lasted until the early decades of the nineteenth century, the most important of which affected the Baltic and Scandinavian regions and other areas in Northeastern Europe in 1708–09, were followed in most countries of Central and Northern Europe by a period when subsistence crises became rarer and affected mortality less (Caselli, 1989, 1991, 1996; Vallin, 1991). Epidemics, however, continued

and typhus, smallpox, dysentery, and influenza were recorded throughout the eighteenth and much of the nineteenth century, though they were less lethal and less widespread than before. These crises began to disappear in the middle of the eighteenth century when Northern and Western countries started to benefit from the first significant results of a more effective struggle against famine and epidemic diseases, particularly thanks to the third 'food revolution' described by Massimo Livi Bacci (1987). After the middle of the eighteenth century, the less serious nature of the crises was reflected by a lower level of mortality and, conversely, by an increase in life expectancy at birth (see **Figure 1** for some representative countries). In fact, life expectancy began to increase in Northern European countries, England, and France, and had reached a figure of between 40 and 42 years by the early nineteenth century, while in the pretransitional period life expectancy was less than 30 years on average. The fall in death rates – particularly in infant ages (see **Figure 2**) – with the consequent increase in life expectancy, had already been apparent for more than a century in those countries when

Figure 1 Life expectancy at birth in some selected countries: trends since the nineteenth century. Source: Own elaboration on the human mortality database, MPIDR, rostock (www.humanmortality.de).

Figure 2 Infant mortality (per 1000) in some selected countries: trends since the nineteenth century. Source: Own elaboration on the human mortality database, MPIDR, rostock (www.humanmortality.de).

(just at the end of the nineteenth century) it was beginning to appear in the rest of Europe, accompanying the first stages of a breakthrough in medicine and improved individual and public sanitary conditions (waste disposal, preservation of surface waters, rubbish collection, etc.). The falling mortality trend continued in Northern countries while some Western countries, i.e., England, Wales, and France, ceased to make further progress in the 50 years between the 1830s and 1880s, during which period life expectancy figures remained more or less constant at the same level (e.g., for France see **Figure 1**). In France life expectancy did not change appreciably in the next 40 years and only resumed its increase toward the end of the 1880s, while in England and Wales the life expectancy increase became rapid and continuous after the 1870s (Vallin, 1991). The reasons for this stagnation have been discussed by a number of authors (McKeown, 1976; McKeown and Brown, 1955, McKeown and Record, 1962; Wrigley and Schofield, 1981). It appears to have been mainly due to the difficulties experienced by those countries in the rather chaotic and uncontrolled early stages of the industrial revolution with its negative effects on the health situation of the working masses and on living conditions and the environment in general. It was only from 1880 onwards, when the first effects began to be felt of the remarkable progress in health care and economic and social development, affecting not only workers but the population as a whole, that life expectancy in those countries resumed its previous upward trend, thanks to the important role played by the falling trend in infant mortality (**Figure 2**).

In Southern and Eastern Europe, where famine and epidemics were still present during the late nineteenth century, mortality rates remained almost at pretransitional levels. It was at the end of the nineteenth century that mortality began to fall significantly in these countries too, so that life expectancy at birth increased from 30–33 to 38–40 years, in 10–20 years (i.e., from 33 to 38 years in Italy from 1881 to 1891, see **Figure 1**).

The general pattern of the differing timescales with which European countries reached different stages of mortality transition clearly reveals the slowness of some of them in achieving a reduction in mortality, and also reflects the time taken by each country to reach the 50-year life-expectancy threshold – in other words, to pass, in Chesnais' terminology (1986), from an outdated to an intermediate mortality regime. Bearing in mind that the normal duration of life before the transition was of the order of 28–30 years, the pioneering countries took about two centuries to reach the intermediate level of 50 years (doubling their starting figure), whereas the latecomers achieved the same result in about half a century. The reasons for this accelerated progress are well-known. At the end of the nineteenth century, the main cause of death in the poorest countries in Europe was infectious diseases (such as typhus, measles, whooping cough, scarlet fever, and diphtheria), particularly deadly in children, which were spread by contamination of the environment or by contaminated food or water and aggravated by malnutrition and the wretched conditions under which the majority of the population lived (Caselli, 1996). Only in the early years of the nineteenth century were a number of these less advanced European countries and also other non-European countries able to benefit fully from the increasingly effective methods

of controlling these diseases which the pioneering countries had developed during the preceding period through slow and patient research.

In the twentieth century, all the countries entered the critical transitional phase in public health, which enabled almost all of them to achieve in only 30 years, the greatest progress ever made in so short a time. As a result, in all these countries the breakdown in the birth–mortality equilibrium, caused by the mortality crises of the two World Wars and the 'Spanish' flu epidemic, was rapidly surmounted (**Figures 1** and **2**). In 1960, life expectancy at birth in the wealthiest countries of Northern and Central Europe had by then reached 70 years for men and 75 for women, while other countries were slightly behind, with an average difference of 4 years between men and women. It was in the 1960s that the mortality rate reached its lowest levels (10–12 per 1000) more or less everywhere and that, following the theoretical pattern of demographic transition, concluded the shift from high to low levels as envisaged in the mortality transition model.

During the transition period there were major modifications in the age structure of the mortality rate, reflecting the passage from the previous regime of high infant and juvenile mortality due to infectious diseases, to a new regime in which adult mortality predominated, with a prevalence of chronic or degenerative diseases. The different phases of this change, viewed both from the overall standpoint and from this structural modification in respect of age and cause of death, moving from the ancient to the new epidemiological regime, were analyzed and theorized in epidemiological domain (Mackenbach, 1994; Omran, 1971).

Epidemiological versus Health Transition

In 1971, following the unprecedented increase in life expectancy in developed countries, Abdel Omran (1971) put forward a theory describing for the first time the decrease of infectious diseases, which had gradually been replaced by chronic diseases. As we have said above, it was labeled 'epidemiological transition' and, initially, comprised the following stages: (1) The 'age of pestilence and famine,' dominated by recurrent mortality crises in which life expectancy at birth was more or less 30 years (a phase indicated in mortality transition pattern as 'pretransitional'); (2) the 'age of receding pandemics,' during which some infectious diseases became less important and the sharp decline in mortality in the early years of life brought life expectancy to 50 years (start of mortality transition); and (3) the 'age of degenerative diseases,' is characterized by the predominance of chronic diseases and the stabilization of mortality at a low level (end of the mortality transition period).

According to Omran, with the Third Age the advances in life expectancy in the mid-1960s slowed down or, in some cases, stopped, with the rise of new endemic diseases, whether degenerative (e.g., cardiovascular diseases, cancers, diabetes, metabolic disorders). France Meslé and Jaques Vallin (2006) consider Omran's division into three ages as accurately reflecting reality up until the end of the 1960s, when he wrote his first article – a period in which the improvements in life expectancy were slowing down, particularly for men.

However, events swiftly belied Omran's model. From the early 1970s on, life expectancy in all Western countries once again began to increase for men too, driven by a clear reduction in mortality for cardiovascular diseases. Following these new behaviors and the resulting increase in survival, Jay Olshansky and Brian Ault (1986) and Richard Rogers and Robert Hackenberg (1987) imagined a 'fourth phase' of epidemiological transition. The first two authors suggested that the mortality model by cause had remained the same because the age of death had shifted forward, while the second two spoke rather of the start of a new era, where the most important advances in survival had been and would be achieved, thanks to the reduction in mortality brought about by the adoption of new and healthier lifestyles.

In 1983, Abdel Omran recognized the existence of one and possibly two additional phases to his initial theory of the epidemiological transition, accepting the suggestions of Jay Olshansky and Brian Ault, but pointed out that the new mortality models would be accompanied by the emergence of new diseases (HIV, Ebola, etc.) and the revival of other former diseases (such as, for example, cholera and tuberculosis).

Omran's identifying a fourth phase of epidemiological transition has been questioned (Fetter, 1997; Meslé and Vallin, 2006). According to France Meslé and Jacques Vallin (2006), his initial idea was based mainly on the conceptualization of the transition from the old stable regime of high mortality in the past to a new stable regime of low mortality. The transition would be protracted and would follow the same pattern of the three phases (or four, according to other authors) without changing the prevailing nosological framework Omran described. Obviously, this interpretation clashes with reality. The new era of advances in survival that had begun in the 1970s was based on a significant change in the epidemiological situation of the cardiovascular revolution. Detailed analyses have shown that this change is something quite distinct from the slump in infectious diseases. For this reason, France Meslé and Jacques Vallin (2006) proposed a substantial modification of Omran's model of epidemiological transition and the reappraisal of it by other authors, suggesting a new model that would follow "the semantic shift proposed by Julio Frenk et al. (1991) and include within the wider concept of 'health transition' an initial phase (that described by Omran) of life expectancy gains, attributed mainly to the decline in mortality due to infectious diseases, followed by a second phase dominated by the decline in cardiovascular diseases, leaving open the possibility of identifying later phases, such as that suggested by Shiro Horiuchi (1999) for cancer and perhaps senescence" (Meslé and Vallin, 2006: p. 250).

Two Phases of the Health Transition in More Developed Countries, Leaving Open the Possibility of a Third

For an overall view that will clearly identify and explain the two main phases of advances in health based on controlling two very different types of pathology that act on equally different ages of decease, we shall refer to the results of some analyses of the last 20 years (Caselli, 1991, 1996; Vallin, 2006). As we have already said, the decline in mortality in Europe began at

different times – due to the different socioeconomic conditions and risk factors in the different countries – while, if we exclude the countries of Eastern Europe, the remaining countries all reached the lowest level of 80 years of life expectancy at birth (79–80 years for men and 84–85 for women) at the outset of the twenty-first century.

If we divide causes of death into broad categories, then, quite apart from the times and levels of mortality, we will find similar models of mortality by cause. In fact, on the eve of the World War I infectious diseases were still by far the main cause of death in all populations, both in countries with a higher mortality and in those with lower mortality rates. If we take all these diseases together (including bronchitis, pneumonia, and influenza), they accounted at that time for 56% in Italy, 49% in England and Galles, and 43% in Norway (Caselli, 1996). In Northern and Southern Europe infectious diseases accounted for slightly more than half of total mortality. Within this group of causes, however, there was a clear geographical differentiation: as we were able to show in a preceding study, gastroenteritis dominated the list of diseases in Southern Europe, while tuberculosis still played a dominant role in Northern Europe, as in the nineteenth century. The geographical differences in the internal composition of infectious diseases were the result of various characteristics of infant mortality and mirrored the distances between countries in terms of development. Gastrointestinal diseases may, in fact, be regarded as a good index of social development, hygiene, and health, in which, at the beginning of the century, Mediterranean countries were still lagging behind the more advanced Nordic countries. Tuberculosis, on the other hand, to which adolescents and young adults were particularly vulnerable, mainly attacked countries in which the urbanization process – already well advanced as a result of the head start of those countries in the field of industrialization – provided a fertile field for the propagation of the disease. At the beginning of the 1930s, when the major health revolution began, infectious diseases, in spite of their genuine decrease, still constituted the principal cause of death. In most advanced Northern countries, where life expectancy already exceeded 60 years, as in the less advanced countries, with a life expectancy of 45–50 years, infectious diseases were still the prime cause of death, representing 35–40% of total mortality.

In the 1930s cardiovascular diseases were responsible in Northern and Central Europe for about 20% of overall mortality. On the other hand, even in the most advanced countries, cancer still be accounted for a modest proportion of total mortality, about 10%. It is of course possible, especially in the case of cancer, which had long been poorly diagnosed, that the available statistics underestimated the real proportion. It is nevertheless certain that we were only seeing the initial stages of the expansion of certain risk factors (cigarette smoking, of course, but also industrial hazards) which were subsequently to contribute to an increase in mortality under this heading. The group of the other diseases, still very well represented, accounted for a large proportion of deaths due to traditional causes, including all diseases specific to early infancy, which remained at a high level until the end of the 1960s.

As we have said, starting at different times and following different patterns specific to each country, the process of transition in the 1960s, just at the end of the major health revolution, had already completely transformed the disease classification of mortality. Thanks to the widespread medical, health, socioeconomic, and cultural progress, along with the introduction of sulfonamides in the 1930s and 1940s, the decline in mortality from infectious diseases accelerated, particularly with the arrival of, first, antibiotics and, then, vaccination. In France, for example, the decline in mortality from these causes was responsible for 10 of the 13.5-year life expectancy gained between 1930 and 1960, while in Italy, where the health transition was further behind, the gain made during the same years may be exclusively traced to the marked decline in mortality from these causes (Caselli, 1996).

In 1960s, cardiovascular diseases had become the paramount cause of death, both in men and women, causing between 30 and 40% of all deaths, depending on the particular country; they occupied the place previously held by infectious diseases. Although these diseases had become more significant, nevertheless, for men, and still more for women, they led to slightly fewer mortalities and contributed to the increased average survival of the population (almost 1 year in France from 1960 to 1970) even in the stagnation characterizing the 1960s, which particularly involved adult and elderly men, which can be primarily traced to unfavorable mortality trends from cancer and violent causes. Cancer, which in the 1960s had climbed to second place, accounted for about 18–20% of male mortality in Northern and Central European countries, and 15% in Southern countries.

It was in the 1970s that the great cardiovascular revolution began. The decline in mortality due to cardiovascular diseases became quickly more significant, first affecting adults and then the elderly, and established itself in all developed countries. This decline is still continuing today and also involves much of the adult population in Asian and Latin American countries (Caselli et al., 2002).

The 1960s, then, marked the most important turning point in health care. It was in this period that cardiovascular diseases replaced infectious diseases in extending life expectancy. France Meslé and Jacques Vallin (2006) point out that this contradicted Omran's theory of the conclusion of the epidemiological transition. Not only did deaths from cardiovascular disease reach ever lower levels from the late 1960s onwards – they had already been diminishing for women in the 1950s – but there was also an inversion in the growth of mortality for some types of tumor – an inversion that in some countries after the 1980s also became marked for tumors of the respiratory tract and for all those causes that France Meslé and Jacques Vallin (2006) call 'man-made diseases' (i.e., lung cancers, alcoholism, car accidents, suicide, homicide). This means that, while the decline in mortality for cardiovascular disease has caused much of the improvement in survival since the 1980s, we may conjecture on the basis of the most recent experience that the positive development of mortality for lung cancer may be, at least for men, at the center of the increase in survival that will take place in the next few decades, leaving open the possibility of identifying later phases, such as that suggested by Shiro Horiuchi (1999).

In fact, for some time it was believed that the different trends for cardiovascular disease and cancer indicated that the death risks for these two groups of causes were in competition with each other and that there had, in any case, been a transfer from

the one to the other as a result of improvements in diagnosis. Later, the clear inversion of the trend of cancer mortality suggested the possibility of other mechanisms and imparted a new stimulus to all the interpretative hypotheses which emphasize the relation between these changes and the economic, social, and health situation. The negative changes in mortality due to cancer, which have continued for many years, can now be more easily linked with the increasing importance of specific etiological factors against which we have no effective means of fighting, either individually or collectively. It is undeniable that the major success achieved in the therapeutic sphere has greatly benefited large numbers of patients, including cancer patients, and prevented the increase in this risk factor becoming an increase in overall mortality. An even more important part has been played, however, by the increasing sensitization of public opinion to health problems; this attitude, by promoting early diagnosis, has enabled full advantage to be taken of the latest treatments and certain risk categories to be eliminated by the adoption of healthier lifestyles.

It is not easy to determine to what extent increasing attention to health problems is due to health education, which is implemented in many countries, or to the changes which have occurred in economic and social structure (Preston, 1975). This latter hypothesis appears to be more soundly based, at least in regard to the majority of diseases, to the extent that the twentieth century has witnessed an extraordinary rise in educational levels and a profound economic transformation which has continually increased the proportion of the population with access to levels of information and standards of living which were reserved in the past for the privileged few. It is no less certain that, irrespective of the genesis of the changes which have occurred, many of those in recent years – and many more to come in the future – have revealed and will continue to reveal new potential resources in the battle against diseases and death.

In sum, the conviction is growing all the time that the determining factors of the fall in mortality have changed in the course of these years. In the first phase of the health transition, which coincided with the first stage of economic development, the direct and indirect importance of the availability of adequate food, the development of health and hygiene, and improvements in living accommodation played a decisive part. In the second phase, which saw the disappearance of the causes of death which were most dreaded in the past and the emergence of new diseases, the determining factors tended to lie in the field of pharmacological discoveries and the modernization of the health service, largely due to a massive investment in health by the public authorities. In this latter phase, however, which coincided with the industrial stage of higher economic development, new risks began to spread, giving rise to diseases such as cancers, against which therapeutic progress proved relatively ineffective at first. More elements suggest that we are on the way toward a new victory which would enable us to overcome these problems too. These are the signs of a development which will enable postindustrial societies to make further progress in life expectancy and in healthy life expectancy and generate a genuine third phase of the health transition. Without underestimating the part played by economic changes, the confirmation and general implementation of this third phase will also depend on the interaction between the new health culture and further improvements in therapeutic resources, particularly for the elderly. The new health culture is active on two fronts: individual and social control of the risk factors and early diagnosis of pathological conditions, and improved health facilities and more efficient forms of treatment and new medical technologies.

The Generalization of the Transition: The Decline of Mortality in Poor Countries

The considerable increase in life expectancy, based on two centuries of progress in combating infectious diseases, was at first limited to European and North American countries, but as early as the first half of the twentieth century also affected some parts of Latin America and Asia. The spread of medical techniques that had been used for years in the more developed countries allowed countries such as Mexico to gain 17 years of life expectancy in just 20 years (1930–50), an advance that had taken Sweden 150 years to achieve.

In a few decades, particularly in the postwar period, cheap but effective methods against infectious and parasitic diseases were widely used in the developed countries and led to a sharp increase in the survival possibilities in much of the Third World. Countries such as Cuba, Costa Rica, Regions as Kerala in India, and a – a little later – China – saw their peoples achieve a life expectancy close to those of rich countries before they had achieved high levels of economic development. The improvements in health care in countries of the South made possible the development of theories and explanatory models of the reduction of mortality, suggesting the importance of considering the many risk factors that, both individually and in combination, play a part in determining the process of the health transition (Mosley and Chen, 1984; Palloni, 1985).

The initial euphoria over the success of vaccines and antibiotics induced the belief that targeted campaigns would be enough to eradicate mortality from the main endemic causes of death. One of the most relevant success stories was Ceylon – present-day Sri Lanka – where in just 2 years (1947 and 1948) life expectancy increased by 12 years following a decisive campaign to eliminate the disease at the behest of the WHO, which involved massive spraying of DDT (Frederiksen, 1960).

From the 1950s to the threshold of the twenty-first century, life expectancy in developing countries overall rose from an average of 41–63 years, with a gain of 22 years, when in the same periods the richest countries saw a gain of no more than 9 years (Vallin, 2006), rising from 66 to 75 years. In this way the gap between the two groups of countries, which was 25 years immediately after World War II, had reduced to 12 years on the threshold of the new century. If we exclude from the group of developing countries sub-Saharan Africa, where even the more modest progress that has been made has recently been compromised by the AIDS epidemic, the difference of 12 years would reduce to 10.

This slowing down of the progress of the poorest countries has dampened the WHO's enthusiasm. It has become clear that imported progress in health care could bring lasting benefits only in the context of policies able to take into account the many factors (social, economic, cultural, and medical) that are highlighted in the theoretic models of experts (Caldwell, 1990;

Suarez-Ojeda and Junes, 1985; Tabutin, 1995). In addition, what proved true in the first phase of the European health transition, which was based on controlling infectious diseases, was still more so in the second phase, when advances in survival were linked to the reduction in mortality from very different kinds of diseases, such as cardiovascular conditions, for example. In this case, it was not possible to simply vaccinate the population against it and reclaim land that was a seat for some infectious diseases. Reducing mortality for modern diseases requires a series of global policies and changes in individual and collective behaviors that are unlikely to be acquired without adequate education. The cardiovascular revolution, which has been ongoing in rich countries and in many developing countries for several decades now – like the battle against cancer – requires, as we have said, individual and collective awareness of the importance of behavioral risk factors, which have been the real driving force in the second phase of the health transition. It has taken many years for all these conditions to have been met in the rich countries and it will require epoch-making changes before this happens in the poorer countries of the world.

In conclusion, the infectious diseases that killed children and adolescents in the main, had to be conquered before modern societies could direct their energies toward those diseases whose victims were adults. A high level of economic and social development was required before there could be the necessary material and cultural tools for eliminating the modern pathologies and preventing new pathologies from appearing or old ones from re-emerging and blocking the process of health transition toward ever higher survival values – and so preventing what happened in the countries of Eastern Europe, and Russia in particular, in the 1980s. These are the only countries that have experienced all the inconveniences of the 'third phase of epidemiological transition' indicated by Abdel Omran in 1983, combining the lack of positive effects from the decline in mortality from degenerative diseases with those produced by an increase in mortality from man-made diseases (Skholnikov et al., 1995).

Mortality of the Oldest-Old

Vladimir Canudas-Romo and Adam Lenart, Max-Planck Odense Center on the Biodemography of Aging, University of Southern Denmark, Odense C, Denmark

This article is a revision of the previous edition article by J.W. Vaupel, volume 15, pp. 10075–10079, © 2001, Elsevier Ltd.

Abstract

"An 80-year-old is as healthy today as a 70-year-old yesterday," such phrases are not uncommon, and we can actually observe that the probability of death of an 80-year-old in Japan in 2009 corresponds to the mortality of a 70-year-old in 1959. This significant change in the mortality level of the oldest-old population, i.e., people 80 years and older, is the focus of this article. Among others, we concentrate on the age patterns, time changes, and population variation in mortality among the oldest age group of the population.

The Oldest-Old: Are They Still 80 Years Old?

Improvements in old age mortality during the second half of the twentieth century have resulted in an unprecedented increase in absolute and relative terms of the oldest-old. This rise in their numbers would not have been possible without a decrease in their mortality rate. As such, there is little resemblance in terms of mortality between an 80-year-old today and a person reaching to that age half a century ago (Sanderson and Scherbov, 2010). As **Figure 1** shows, the mortality level of 80-year-olds in 2010 in the USA corresponds to the mortality of 71-year-olds in 1950. Japan shows a more extreme case with an age gap of 10 years between those in 1959 that experienced the same mortality level as 80-year-olds in 2009.

For countries with longer historical time series of mortality, we can already see moderately improving mortality conditions as early as in 1900 for the oldest-old. In France and Sweden at ages 63 and 70 in 1900, and 69 and 72 in 1950, respectively, are observed the same levels of mortality of an 80-year-old in 2010. In other words, a transition of 11 years in France (from age 69 in 1950 to 80 in 2010) and 8 years in Sweden in the second half of the century as opposed to 6 and 2 years in the first half of the century, respectively. In these countries as well as in other high-longevity countries, the second half of the century was characterized as one of drastic mortality changes for the oldest-old.

How Many Oldest-Old Are There?

The differential in ages that have the same mortality levels over time is only one indicator of the changes in mortality observed in the group of the oldest-old. The number of survivors or mortality until the age of 80 years, and the remaining expected number of years of life after the age of 80 years, or life expectancy at age 80, complement the information provided by the level of mortality at this age. Of these three spectrums of mortality (past, present, and future; or mortality before, current, and after age 80), the largest mortality differential is the great number of extra survivors attaining old age now as opposed to in the past.

Figure 1 Ages in the twentieth century that show similar levels of mortality as 80-year-old females and males in 2010 for the USA, France, Sweden, and Japan.

Figure 2 Life table distribution of deaths after the age of 50 years in high-longevity countries in 1900, 1950, and 2000.

Aggregating all the mortality information from high-longevity countries, as if it was one population, allows us to observe clearer trends in mortality for the oldest-old (we use this aggregated data in the rest of the article unless we explicitly refer to a country). **Figure 2** presents the bell shape characteristic of the distribution of deaths centered on the modal age at death, or age where most of the deaths occur.

In 1900, the modal age at death was 73.4 years, which changed to 78.8 in 1950 and 89.7 in 2009. In the second half of the twentieth century, there is a faster shift toward older ages for the bell shape in the distribution of deaths. This shift reflects the amble improvements in mortality in ages above the modal age seen in the recent past. High-longevity countries have a life expectancy at birth of 81.5, which is beyond the threshold age of the oldest-old group of 80 years. In other words, a child born today in high-longevity countries will live on an average of 81.5 years if current mortality conditions remained without change in the future. However, it is 8.2 years later where the modal age at death or age with the highest concentration of deaths is found (Canudas-Romo, 2010). The burden in hospitals, nursing homes, and public health in general is thus intensified at ages around the modal age at death.

The highly debated rectangularization of the survival function is easily refuted by looking at the trend over time in the modal age at death. The current changes are better described as a shift in the bell shape of mortality around the mode, while the deviation from the modal value has decreased. The standard deviation beyond the modal age in high-longevity countries has changed from 4.9 in 1900, to 4.7 in 1950, and 3.6 in 2010. Some have seen this as the beginning of the end of longevity or the arrival to the limit of longevity, while a more accepted perspective argues in the direction of a double phenomenon of shifting and compression of mortality.

Age Pattern of Mortality after the Age of 80 Years

While mortality increases exponentially in younger adult ages, the probability of death levels off at extreme old ages. The well-known Gompertz–Makeham mortality model captures well the pattern of mortality for young adults between ages 30 and 90, but it needs to be modified to capture the plateau of the age-specific death rates of the oldest-old (Missov and Lenart, 2011). A logistic curve-type in the female and male age pattern of mortality can be seen in **Figure 3** (Thatcher et al., 1998). In this Figure, the estimate of a constant death rate of 0.7 above age 110, stemming from supercentenarian research, is also included (Maier et al., 2010).

Frailty theory has helped explaining the bending of the mortality curve at old ages. This theory considers a population to be composed of heterogeneous individuals with various degrees of mortality. Individuals with a higher level of mortality are likely to die younger, and the overall population level mortality is then driven by the lower level of mortality of the remaining persons.

The larger pool of oldest-old persons has also increased the variation of mortality at older ages and changes in the age pattern of mortality are already observable. Octogenarians in high-longevity countries experienced average annual mortality improvements of 1.2% between 1950 and 2009. For the same period, nonagenarians experienced average annual declines of 0.6%. However, the mortality of centenarians is yet to improve. As a consequence of the mortality shape at old ages, the groups of centenarians and supercentenarians have increased at unprecedented numbers.

The cause of death structure of the oldest-old differs from the causes of death at younger-old ages. Multiple causes of death are not uncommon in death certificates at the oldest-old ages. Though broadly speaking, in spite of the major decline of cardiovascular mortality at the oldest-old ages, heart failure, coronary atherosclerosis, and stroke are still among the leading causes of death. Other important causes of death that distinguish the oldest-old from the younger old are pneumonia, influenza, septicemia, mental disorders, nutritional deficiency, and accidental fall. Diseases that tend to develop prematurely in some high-risk individuals at younger ages such as malignant neoplasms, acute myocardial infarction (particularly for males), hemorrhagic stroke, chronic liver disease and cirrhosis,

Figure 3 Female and male age patterns of mortality for high-longevity countries. Including estimates of mortality for ages beyond 110, or supercentenarians, at a constant level of 0.7 (equivalent to a probability of death of 0.5; Maier, H., Gampe, J., Jeune, B., Robine, J.M., Vaupel, J.W., 2010. Supercentenarians. Demographic Research Monographs 7 (XVI), 325. http://dx.doi.org/10.1007/978-3-642-11520-2.).

diabetes mellitus, and multiple sclerosis are less prevalent at oldest-old ages (Horiuchi, 2007).

Gender Differences in the Mortality of the Oldest-Old

The higher male to female mortality found at younger ages is also observed at the oldest-old ages (Oksuzyan et al., 2010). As a consequence, the ratio of oldest-old females compared with oldest-old males is particularly prominent. Among developed nations, the extreme disparity between numbers of females and males above age of 80 years is found in Germany with 227 females per 100 males. Eastern European countries have also very high numbers of females as compared to males at older ages. At the other extreme, in Iceland there are only 150 females per 100 males followed closely by Israel and Australia. The female to male ratio gains intensity with age; if all the mortality information from high-longevity countries were taken together, at age of 80 years the ratio of females to males would be 146 females per 100 males, by age of 90 years it increases to 250, for 100-year-olds we have 547, and at age 110 a ratio of 772. Once more referring to high-longevity countries, females surpass their male counterparts with 44 920 females above age 100 in 2009, as opposed to 7219 males. The maximum age attained at death by a person follows also the female–male gap differential with Jeanne Calment (France), a woman reaching age 122 and a half when she died in 1997 (Vaupel, 2010) and Jiroemon Kimura (Japan), a man reaching age 116 when he died in 2013 (although the age of this person remains to be well documented).

The female–male life expectancy gap has been changing over time too. The contribution of the oldest-old age group to explaining this life expectancy gap between sexes has increased over time. A combination of cancers, respiratory and cardiovascular diseases is identified as the causes of death responsible for the gender-gap in remaining life expectancy at ages beyond 80.

Determinants of Oldest-Old Longevity

Blue zones was a term coined by Michel Poulain and Gianni Pes to identify a region in Sardinia (Italy) where the number of oldest-old, particularly centenarians and supercentenarians, is unusually high. This has been popularized into a less scientific, but still intriguing, search for regions in the world where mortality at oldest-old ages is significantly lower: Okinawa (Japan), Nicoya (Costa Rica), Ikaria (Greece), and Loma Linda (United States) can be listed among them. Although each group has its own reasons for their aging success, some common traits for all groups are they are physical active communities, where people have a vegetable-based diet with a moderate alcohol consumption but without overeating habits; of importance is also that they have a reason for living and waking up every day; and that they belong to a group (faith, friendship, or/and family).

Being born with the right set of genetic information has also been suggested as a key element to reach old age and to have lower mortality risk than your peers; for example, carriers of the ApoE ε4 allele have higher mortality than none carriers, particularly among those aged 90 and more. Similarly, variants of the FoxO gene have been found more frequently in centenarians than in 90-year-olds suggesting a strong association of these genes with human longevity (Kenyon, 2010). Although, these associations have been

found in centenarians coming from different ethnic groups, the mechanism of aging and how the genes delay this process need to be further explored.

Theories of Oldest-Old Mortality

The most prominent evolutionary theories and a brief description of their main ideas can be shortly mentioned (Kirkwood and Holliday, 1979) as follows:

1. Mutation accumulation: Mutations that decrease the fitness are selected against, but germ line mutations that are expressed in older ages are not regulated by evolution.
2. Antagonistic pleiotropy: Genes that offer advantages to survival or reproduction in younger ages and are deleterious in older ages are not selected against.
3. Disposable soma: There is a trade-off between reproduction and maintenance. The primary function of the somatic cells is the reproduction of the organism. However, only finite resources are available for organisms, and their most efficient use is to invest in reproduction and less in repair.
4. Grandmother hypothesis: Long postreproductive human life span is justified, if older relatives contribute to the reproductive success of their progeny.
5. Insurance against indeterminacy: Higher life expectancy decreases the probability of death in the reproductive ages.

Current evolutionary theory acknowledges that postfertile life span is an evolved trait. As evolutionary selection optimizes fitness (number of surviving offspring) and not the length of life itself, evolutionary theory does not suggest any upper limit of human life span. Demographic observation also supports the notion that a 'Wall of Death' that cannot be exceeded does not exist. According to the mutation accumulation, antagonistic pleiotropy and disposable soma theories, the timing of old-age death is indeterminate. However, the grandmother hypothesis and insurance against indeterminacy hypothesis postulate that mortality in the postreproductive ages could have evolved to increase fitness in childbearing ages (Levitis et al., 2013).

Data and Future of Oldest-Old Mortality

Problems with vital registration systems, census and population registers, divide countries into those where it is possible to accurately calculate death rates and those where it is not. As such, in many developing nations, it is less clear which type of mortality levels are found in the oldest-old population. For example, in several Latin American countries the mortality of the older population is lower than in more developed nations: for example, Costa Rican death rate between ages 80 and 84 in the period 2005–09 was 61.8 per 1000, which is lower than the death rate of 65.9 per 1000 observed in Sweden for the same age group and time. Costa Rica has very well-documented data, however, other countries in the region have similar death rates, which have prompted debate among specialists about the accuracy of the information in the entire region. Other regions of the world have even greater problems in their data collecting system with the extreme in African countries, where data can be trusted only in very few cases.

Countries with deficient mortality and population historical data use relational models as an alternative to assess their mortality levels, now and in the future. The output of these relational models that are created from historical information from countries with reliable data are age patterns of mortality that decelerate with age at the oldest-old ages.

For countries with accurate historical mortality information, the Lee–Carter model is currently the most widely used mortality projection model in demography. According to this model, the mortality level of the oldest-old is likely to decrease in the future. However, this model might even overestimate their future death rates as it assumes a constant rate of improvements in mortality, which does not match the experience observed in the oldest-old age group. Alternative procedures have been developed recently to more systematically capture the rapid decline of mortality of the oldest-old. Examples of alternative forecasts in individual country forecasts are including the information of the best performer, or averages of all countries with similar trends.

To further understand the oldest-old mortality in the present and to prepare for the future, priority should be given to collect the right data of both, current and past, health and exposure information. A multidisciplinary effort will be required, where scientists from the fields of humanities, biology, medicine, and mathematics collaborate to advance the knowledge of the secrets of oldest-old low mortality and long life.

Mortality: The Great Historical Decline

Tommy Bengtsson, Lund University, Lund, Sweden

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The timing of the great mortality decline was strikingly similar in the countries of Western and Northern Europe, despite differences in their individual economic structure and development. The decline started in the middle of the eighteenth century, became more pronounced around AD 1800, and then continued. The history of mortality decline in North America was similar. Life expectancy at birth starting at around 35 years, increased about 1 month per year between AD 1750 and 1840, and thereafter increased by almost 3 months per year to reach more than 80 years by the end of the nineteenth century. With the great mortality decline followed a change in the composition of the causes of death, away from pestilence, over receding pandemics, to man-made diseases. Few scholars today will argue that a single factor, like economic growth, was the main determinant of the great mortality decline. Economic growth was perhaps not a major determinant, at least not in the initial stages of the great mortality decline and perhaps far less than expected during the later stages as well. In fact, the causes are multifactorial and vary from the start of the decline to the present day.

Features of the Decline

Our knowledge about the initial stages of mortality decline is not only based on data from the Nordic countries, which have had historical data of age-specific mortality rates far back in time due to the early implementation of population censuses, but also from data derived from England, France, and other countries, where information has been derived through reconstructions of national samples of parish data. From these sources we know that mortality in the Western world started to decline around AD 1800, a decline that identifies the start of the demographic transition (Davis, 1945; Notestein, 1953). It is, however, less well known that mortality had already started to decline throughout Europe prior to the mid-eighteenth century (Perrenoud, 1984); in England the decline started even earlier, from AD 1720 (Wrigley et al., 1997), with a similar development in North America (Fogel, 1994). Thus the timing of the great mortality decline was strikingly similar across the countries of Western and Northern Europe, starting, albeit at a lower rate, well before 1800. This timing could also be substantially similar within different areas of a country, as in Sweden (Fridlizus, 1984).

We know that this decline began with a fall in the rates of infant and child mortality. While infant mortality continued to decline in the Nordic countries throughout the nineteenth century, it leveled off in Western Europe and remained stable until the end of the nineteenth century, and then dropped rapidly as in all other Western countries. Thus, two patterns of the historical infant and childhood mortality decline can be identified: a Northern pattern with declines essentially throughout the nineteenth century and a Western one with a leveling off during the nineteenth century and a new decline after the 1880s (Perrenoud, 1984). The decline in adult and old age mortality became more pronounced during the course of the nineteenth century and became more rapid after World War I. It slowed down around 1950, to become more rapid again in the 1970s and has continued declining since then.

The great mortality decline was characterized by a change in the composition of the causes of death, shifting away from pestilence, via receding pandemics, to man-made diseases. In fact from Swedish records we know that the pre-1800s decline in infant and child mortality was entirely due to a reduction in deaths from smallpox, which was a very common childhood disease in the eighteenth century (Fridlizus, 1984; Sköld, 1997). The theory of epidemiological transition, distinguished between three development patterns: the classical (Western) pattern described above; the accelerated pattern; and the delayed pattern (Omran, 1971). They are distinguished by differences in timing and speed. The decline that took 200 years in the West started 150–200 years later in the Third World, but took less than 50 years to complete. There are still many countries where the great mortality decline has been delayed and where the possibility still remains to reap gains from low mortality.

As a consequence of the decline in mortality, life expectancy started to increase, from around 35 years in the mid-eighteenth century, to more than 45 years in the 1850s, and to almost 55 years at the end of the nineteenth century in a number of countries. Mortality in the Western world continued to decline throughout the twentieth century, and in best practice countries, life expectancy increased at a rate of about 3 months per year for females, (slightly less for males), to reach more than 80 years in AD 2000 (Oeppen and Vaupel, 2002). Countries with lower life expectancy levels, like Japan and China, had far faster improvements in life expectancy during the catch-up periods, sometimes more than 1 year per calendar year.

Explanations of the Mortality Decline

Two types of factors, *period* and *cohort*, have been put forward in explaining the decline. While period factors affect the entire population at the same time regardless of age, cohort factors influence a certain cohort, typically a birth cohort, over the entire life course. One should also make a distinction between factors that rely almost entirely upon the *actions of man* and those *beyond deliberate human control*. Interestingly enough, cohort explanations, which were in focus in the 1920s and 1930s, were replaced by period explanations in the 1950s, and seem to be enjoying a revival.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31043-1

Period Explanations

A widely accepted multifactorial explanation (United Nations, 1953) is based on period factors such as public health reforms, advances in medical knowledge, improved personal hygiene, as well as rising income and rising standards of living. This explanation is consistent with the demographic transition theory.

The demographic transition theory was once one of the most widely accepted 'truths' in social sciences and one of the main pillars of the UN view of how to promote heath improvement in developing countries. It stated that mortality was high and fluctuated strongly before the demographic transition. The transition was said to begin with a decline in the general level of mortality and with a dampening of its fluctuations. This was regarded as a consequence of a modernization of the economies (the agricultural and industrial revolutions). A rapid increase in population size would follow, since fertility declined much later than mortality, due to slow response from the institutions and norms that influence fertility (Davis, 1945; Notestein, 1953).

The idea of a stable level of mortality prior to modernization is a central feature in the theory, but before the mid-eighteenth century the mortality level was far from stable, as was shown for England by Wrigley and Schofield (1981). Similar patterns had been demonstrated by many other scholars as well, but only for individual parishes or institutions, or for smaller regions like Southern Sweden (Bengtsson and Oeppen, 1993) or Northern Italy (Galloway, 1994). Since the mortality level prior to the great mortality decline was not stable, it is not appropriate to use it to identify the beginning of the demographic transition (Bengtsson and Ohlsson, 1994).

The link between modernization and the mortality decline, central to the demographic transition theory, is far from obvious. Typically, mortality began to decline at least half a century (or earlier) before marital fertility started its own long-term decline, and long before living standards for the ordinary man started to improve – another criticism of the demographic transition theory. Sweden is a good example of this, since living standards for workers started to improve steadily only after industrialization around 1860 – more than 100 years after mortality started its slow decline and more than 50 years after the decline became more rapid. Also for countries like Germany and France, which experienced the industrial take off earlier than Sweden, the mortality decline preceded improvements in living standards. In fact it is not even clear that improvements in living standards preceded mortality decline in England, since evidence suggests that living standards for workers declined during the eighteenth century, at the same time that mortality slowly started to go down (Wrigley and Schofield, 1981).

On a broader front, McKeown (1976) questioned the multifactorial explanation of the great mortality decline. He argued that a single factor, namely better nutrition, could explain almost the entire great mortality decline. His criticism was based on a study of cause-specific mortality in England and Wales from 1838 to 1947, where he observed that two-thirds of the mortality decline was due to a reduction in the prevalence of infectious diseases.

McKeown argued that medical advances had little influence on mortality trends before the breakthrough of sulphonamides and antibiotics in the 1930s and the 1940s. In earlier periods the only disease that one could cure was diphtheria. Very few deaths, however, were due to diphtheria and it was already retreating when the antitoxin came into use around 1900. For periods before 1838, McKeown argued that inoculation and vaccination for smallpox had little or no impact on the general mortality decline. Vaccination started in England at the end of the eighteenth century, but it was not widespread until after 1840, at which time it became available at public expense. Inoculation stated earlier but had little impact, according to McKeown.

In the Nordic countries, smallpox mortality went down well before vaccinations started in the first years of the nineteenth century and long before vaccination became compulsory in Sweden in 1816 (vaccination became more common in the 1820s when some 40% of the population of Sweden were vaccinated). Although mortality due to smallpox was quite rare in Sweden by the time vaccinations started in 1801, it continued to be fatal for many decades. Thus although vaccination had nothing to do with the decline of smallpox mortality, it perhaps prevented it from coming back on a large scale.

Turning to inoculation, another potential prevention against smallpox, only about 50 000 individuals were inoculated between 1750 and 1800 in Sweden (Sköld, 1997). If inoculation provided total safety against death from smallpox, some 7500 would have been saved, assuming a fatality rate of 15%. This saving should be compared with the 300 000 who died from smallpox in Sweden during this period. Thus neither inoculation nor vaccination was of major importance for the initial mortality decline but it is possible that vaccination ensured that the disease never came back. Whether it also eradicated smallpox is, however, doubtful, since the disease was already showing a tendency to become milder over ti1me.

The improvement of personal hygiene may have had some effect on mortality in England and Wales after about 1880, when a decline in intestinal infections coincided with substantial improvements in water supply and sewage control, which must have reduced the incidence of waterborne infections. Since changes in mortality from intestinal infections were only a smaller part of the general mortality decline prior to, say, AD 1870, the general reduction must have been mostly due to factors other than improved personal hygiene, according to McKeown. For the same reason the type of public health measures discussed above must have had little impact on the great mortality decline prior to 1870 and only a partial effect afterward. Other public health measures (such as the breastfeeding campaigns that took place in Sweden in the 1830s and later) were not discussed by McKeown. Fridlizus (1984), however, has argued that for Sweden, these campaigns might very well have had an impact on infant mortality, but started much later than the decline in mortality. Incidentally, childhood mortality went up somewhat during the period when the breastfeeding campaigns began.

Helleiner argued in 1957 that the population of Western Europe must have increased from the mid-eleventh century to the late thirteenth century and from the mid-fifteenth century to the end of the sixteenth century. The population increase observed in the eighteenth century was therefore not unique except that mortality decline started from a higher level and went on longer than before. Helleiner and other scholars have argued that these changes in mortality were spontaneous (natural), and in 1973 the UN added natural factors as a fifth determinant of the great mortality decline. Later, Fridlizus (1984), Perrenoud (1984), and Schofield (1984) asserted

that a change in the virulence of pathogens initiated the great mortality decline. The basic idea is that the virulence of pathogens changes spontaneously over time. Virulence in an organism is generally understood as its ability to overcome host defences. At this point it is important to note that some pathogens develop more quickly in a malnourished host while others do not depend on such circumstances to produce very high mortality. Influenza epidemics, for example, are neither created nor sustained in malnourished persons.

McKeown's main argument on this issue is that the initial decline in mortality during the latter part of the eighteenth century was an integral part of the great mortality decline, which continued for the next two centuries; and therefore it cannot be attributed to a spontaneous reduction in the virulence of pathogens. According to McKeown, only nutrition remains as a plausible explanation not only for the decline in infectious diseases from the mid-nineteenth century onwards but also for the initial phase of the mortality decline. This reasoning is part of McKeown's attempt to find one explanation for mortality decline as a whole.

While Helleiner regarded the virulence hypothesis as a period explanation outside of man's control, Kunitz (1986) did not agree. He argued that the disappearance of epidemics, such as plague, typhus, and smallpox, is associated with the growth of stable governments, the expansion and integration of nation states, and the emergence of disciplined armies in the seventeenth and eighteenth centuries. These advancements made it possible to control epidemics by means of isolation and better hygiene. Whether this also applies to smallpox is not clear, since families with children having the disease were never isolated, at least not in Sweden, even though such ideas were put forward (Sköld, 1997). Kunitz also put forward the argument that population growth and loss of regional and local isolation converted epidemics into relatively more benign childhood diseases including the nonspecific pneumonia–diarrhoea complex, which became relatively more important when epidemic diseases declined. As a consequence, mortality became more dependent on nutritional status and adequate adequate nursing. Poverty, crowding, poor sanitation, and hazardous work conditions became likewise more important as determinants of death, particularly in the cities. As a result, the eighteenth century saw a divergence in the life expectancy of the upper and lower classes, according to Kunitz. His empirical evidence for this conclusion is, however, rather weak since it is only based on a comparison of aggregate infant mortality rates in England, France, Sweden, Germany, and Spain, and with rough estimates of the standard of living in these countries at the end of the eighteenth century.

The first part of Kunitz' explanation, namely the control of epidemics by means of isolation and better hygiene, is much in line with Easterlin's argument that technology (in a broad sense) was the main determinant of the great mortality decline (Easterlin, 1999). Easterlin argued that the mortality decline from the late nineteenth century onwards was not due to economic growth and market developments but to public policy initiatives and new institutions based on new knowledge of disease. This could explain the simultaneous mortality patterns in countries with clear differences in economic development, in the latter part of the nineteenth century onwards.

Cohort Explanations

Cohort explanations of the mortality decline refer to features that initially affected only certain young age groups but that may have long-lasting effects for the groups involved. Net nutrition is seen as the main determinant of the development of cells, which is most rapid during the fetal stage and which diminishes gradually until the body is fully developed at an age around 20. Net nutrition is what is left for the development of cells, after the nutritional claims for other life-supporting activities and work are accounted for. A low net nutrition could thus either be due to low nutritional intake or to additional claims coming from diseases. Also, many diseases not only make their own claims on nutrients but also make it more difficult for the body to absorb nutrients in general. This is the case for infectious diseases. If cells and organs do not develop, children may become stunted, shorter in general, and less healthy. Thus we can basically differentiate between two types of cohort explanations for the mortality decline, namely increased nutritional intake during the fetal stage and/or early years of life; and decreased claims during the fetal stage or early years of life due to a reduction in diseases in the mother or the child.

The importance of early childhood conditions for health in later life has probably been well known since time immemorial. The idea is that each generation seems to carry along the same relative mortality from childhood to old age. This was also what the first studies of the great mortality decline emphasized (Kermack et al., 1934). Improvement in health among infants and children brought about a general decline in mortality. The focus then turned to period factors in the 1950s, as discussed above. Both medical and historical research in this area has expanded rapidly over the last couple of decades (for overviews, see Elo and Preston, 1992; Kuh and Ben-Schlomo, 2004). In this connection, the work by Barker (1994) has been of major importance. He has summarized the medical evidence of the importance of nutrition for the fetus and the new-born infant for the health of the adult. Fogel (1996) has advocated these ideas in historical research perhaps more than anyone else. In addition, Preston and van de Walle (1978), for urban France, and Fridlizius (1989), for Sweden, emphasized the importance of cohort factors in mortality decline, though more in the vein of Kermack and his colleagues.

Steckel (1983) and Fogel (1996 and previous work) use final body height as a measure of net nutrition and health during childhood. Individuals who had well nourished and healthy mothers and were well nourished themselves during the fetal stage, have a lower risk of death during infancy. If they are well nourished and healthy, their cells and organs develop better and they are taller and live a longer life. Since net nutrition and not gross nutrition determines health, there is no direct link between gross nutrition and height. Improvements in health and height may either be a result of better nutrition (better diet), or fewer claims due to diseases. Thus a decline in the prevalence of smallpox, for example, has a positive effect on height and extends the lifespan, everything else being equal. The problem is that it is difficult to evaluate how much of the improvement in health is due to diet and how much is due to other claims. Calculating diets for premodern populations is a difficult task (Fogel, 1996), and it is even more difficult to calculate claims. Still, Fogel and others claim that historical

records, fragmentary as they are, show similarities between trends in height and gross consumption, indicating that the trend in claims has been of minor importance (Fogel, 1994, 1996; Floud et al., 2010).

Undernourishment, whether due to a low or badly composed intake or due to an increased claim on nourishment because of disease, may lead to a stunting of height or weight as well as to illness, disease, and mortality later in life, rather than increasing mortality in the immediate future. The immediate relationship – i.e., the period link between economy and mortality – is therefore much weaker than Malthus believed, according to Fogel. The rather weak short-term relationship often found between prices and death for many European countries, shown by Lee (1981), Galloway (1988), and others, supports this interpretation (Fogel, 1994). Thus, cohort factors matter more to the mortality decline than period ones, according to Fogel.

A warning against an uncritical use of cohort mortality notions is implied in the findings of Fridlizius (1989), who has shown that the mortality of the Swedish cohorts born in the beginning of the nineteenth century deviated greatly from the anticipated mortality trends, given their mortality at younger ages. He called them 'deformed cohorts' and saw the excess mortality for men as due to high levels of alcoholism during the 1830s and 1840s. Such life-styles lifted their mortality above their 'programed' level. Other analyses of aggregate cohort mortality data also bring into question, any strong cohort effect of conditions prevailing in early life.

While Fogel was mainly concerned with chronic malnutrition, we may also note that temporary disturbances in nutrition, in particular during some periods at the fetal stage, may also have long-lasting effects on health, since later improvements cannot always compensate for prior loss (Barker, 1994). Therefore, temporary malnutrition due to lack of nutrients or to an increased disease load, whether of the mother or of the child, may have long-lasting effects on health and lifespan. It has, for example, been shown that in Sweden the disease load in the first year of life has a strong impact on mortality from airborne infections and other diseases in later life (Bengtsson and Lindström, 2000). Consequently, elimination of temporary malnutrition, which is still a major problem in many countries of the world, may cause another long-term cohort decline in mortality.

Mortality Fluctuations

Another feature of the great mortality decline is that mortality fluctuations became much smaller in the nineteenth century than they were previously. Views on its consequences for the balance between the population and the economy in preindustrial society and its effects on mortality decline have been controversial. There are two schools of thought and they have reached very different conclusions. According to those who analyze mortality crises (Meuvret, 1946; Goubert, 1965), the reduction in such crises was a major factor behind the secular decline in mortality. This view gained support during the 1960s and 1970s. Wrigley and Schofield (1981), in their analysis based on a large national sample of English parishes, showed, however, that the elimination of crises accounted for only a small fraction (about 10%) of the secular decline in mortality. Many others also obtained similar results (see Ortega Osona, 2000, for an overview). This view is now questioned by Ortega Osona, who has found that the conclusion of Wrigley and Schofield holds true for England but not for Northern Italy and New Castile, where the reduction of the variability in mortality was found to be important for the initial decline in mortality. Analyses of determinants of mortality fluctuations, by age and gender and for different socio-economic groups using longitudinal individual-level data, have expanded in the last decade (Bengtsson et al., 2004) from previous analyses made at the macro level without such details (Lee, 1981; Galloway, 1988).

The Socioeconomic Gradient in Mortality

In the last decades, increasing health differentials between social groups have received a lot of attention (Marmot, 2004). It has been argued that we become sick not only because of low income, but also because of increasing income differentials (Wilkinson, 1996; Wilkinson and Picket, 2006). Social differences in health have in recent times diverged not only in low-income but also in high-income countries. This is in stark contrast to the early postwar period when improvements in life expectancy in many countries made health authorities, health scientists, and politicians believe that social differences in mortality had started to converge. The conclusion at the time was that inequality, when measured as death rates, was on a steady decline, possibly even on the brink of disappearing; the reason being access to prevention and medication at low costs. Yet another view was that class differences in mortality had always existed but had remained more or less constant (Cassel, 1976; Link and Phelan, 1996; Marmot, 2004). The underlying hypothesis is that those who have greater access to economic resources will always be less afflicted, regardless of the nature of the disease (Link and Phelan, 1996).

The question is then whether health differentials have converged, diverged, or stayed more or less constant. Due to a lack of coherent data covering long time periods, our knowledge has been based on highly incomplete evidence from a variety of locations at various points in time. A recent publication, however, summarizes the results from seven new studies of locations in Western and Southern Europe, the United States, and Canada, for which individual-level longitudinal data exists for long time periods (Bengtsson and van Poppel, 2011). Most of these studies also cover large parts of the twentieth century, for which such micro data hitherto had largely been lacking. Taken together, they have a wide geographic coverage and a very long time horizon.

Geneva, with a labor force of more than 20 000 in the watch-making industry alone in 1800, saw huge but declining social differences in mortality during its nineteenth-century industrialization (Schumacher and Oris, 2011). The workers in the sawmill town of Sundsvall in Northern Sweden faced higher mortality than farmers, but had the same levels of mortality as the upper classes in the town itself (Edvinsson and Lindkvist, 2011). In Saguenay, Quebec, with a growing aluminum and pulp industry, mortality was about the same for all groups except farmers, who had significantly lower mortality up until recent times (Gagnon et al., 2010). In a rural area in Scania in Southern Sweden, with some

emerging industry after 1860, workers and the affluent farmers had the same mortality in working ages up until 1950, when they diverged (Bengtsson and Dribe, 2011). In Alghero, a port town in Sardinia, the social differences in mortality among children were substantial but did not increase as it became industrialized (Breschi et al., 2010). Instead, these social differences either stayed constant or declined. The situation in the Netherlands, for which data covers a large part of the country, both urban and rural, was similar. The social differences found for earlier cohorts remained the same or diminished slightly over time (Schenk and van Poppel, 2010). While the absolute differences in infant and child mortality between social groups in the United States have diminished over time, the relative differences persist and have possibly expanded a bit (Haines, 2010).

Taken together, in no case is it possible to find evidence for worsening conditions leading to higher mortality and/or larger social differences in mortality during the industrialization phase. In one case in rural Scania, we find increasing social differences in adult mortality after 1950. A social gradient in mortality is indeed found in urban areas, notably Geneva and Alghero, but these differences date further back in time, and in Sundsvall there were no differences at all. Instead, mortality was higher in urban than in rural areas for all social groups, a common finding referred to as the urban mortality penalty. The finding that social differences in mortality were small (except in cities), in preindustrial agricultural societies that were included in the studies mentioned above, is consistent with findings for historical England both at the macro level (Wrigley and Schofield, 1981; Hollingsworth, 1957; Livi-Bacci, 1991) and at the micro level (Clark, 2007).

The reason for the lack of social differences in the past is most probably because mortality in communicable and often virulent diseases was high during this period. Almost all groups were exposed, and medical treatment was inefficient. The difference between urban and rural areas was therefore probably the result of differences in exposure, not resistance. Today, the disease pattern is entirely different, even though pandemics strike now and then. Life style factors, such as smoking, diet, and exercise, have become increasingly important. Diseases are treatable and means of prevention are known.

Summary

Few scholars today will argue that any single factor was the main determinant of the great mortality decline. Of course, it is no coincidence that the greater resources made available by the transformation of our economies in the eighteenth and nineteenth centuries runs parallel with the great mortality decline and with the fertility transition as well. In a millennial perspective, these events took place at about the same time. That is not to say that there is a close relationship between the economy and the great mortality decline. On the contrary, economic growth is not likely to be even a major determinant, either before the decline or in its initial stages, and was also perhaps far less than expected during later stages. Instead, the causes are multifactorial and vary from the start to the end of the decline.

Parts of the initial decline may very well have been the result of pure luck – a spontaneous decline in the aggressiveness of smallpox pathogens that were a part of an old demographic pattern – and not a result of a modernization process or vaccination. The development and compulsory use of vaccines probably did help prevent the return of the disease. Improvements in nourishment and in the care of children had long-lasting effects on the lifespan. Advancements in water supply and sanitation, as well as better housing, contributed to the decline from the second part of the eighteenth century onwards. Medical development in the twentieth century prolonged life. The fact that health is determined by net nutrition, defined as nutritional intake minus claims, and that claims are due partly to diseases, makes it difficult to evaluate the determinants of the mortality decline. The influence of conditions in childhood and other temporary factors on mortality at older ages, also adds to the complexity of the issue. The impact of each individual factor is therefore very difficult to measure and requires long time series of high-quality data. Several variables, like the virulence of pathogens and the claims on nutrients due to disease, can at best be estimated indirectly, if at all. The analyses based on highly aggregated longitudinal data have identified the problems and directed us toward the solutions. It is, however, doubtful that solutions will be found at that level of analysis. Perhaps the use of longitudinal microdata will serve as an important complement, as it has in other areas.

Thus, the cause of the great mortality decline is multifactorial and the importance of the various factors changes over time. These factors also influence each other. For example, health is both a cause and a consequence of net nutrition, and this makes it extremely difficult to measure the impacts of each factor. Still, it seems very unlikely today that the initial phase of the great mortality decline was mainly a result of an increasing standard of living and of intervention by man. From the late nineteenth century onwards, it is likely that improved nourishment and various interventions had an impact on the decline. One might therefore argue that the initial decline was not a result of modern developments but rather part of an old pattern, where the level of mortality varied. If this pattern had continued, one could have anticipated an upswing in mortality during the latter part of the eighteenth century, and in fact such an upswing started in several European countries around the middle of the century, although it was limited. At present, we know that improved nourishment, personal care, and various public health measures mattered. Thus, we may speculate that it was not the initial mortality decline that was a result of the development of modern society, but rather the absence of an otherwise expected increase. This leads us to a new generalization of the demographic transition, where the pretransition stage is characterized by changing levels of mortality that were not controlled by man, with population growth varying, as did nuptiality and fertility. From around the middle of the eighteenth century this pattern was broken and man began to determine the levels of mortality as well as fertility.

Mother-Child Communication: Cultural Differences

Carolin Demuth, Aalborg Universitet, Aalborg, Denmark

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Communication with children plays a crucial role not only for cognitive and social-emotional development but also in a more general sense for an understanding of self and self in relation to others. Research from linguistic anthropology and cultural developmental psychology have shown that there exists a great variety of cultural genres of communicating with children that are in line with the relevant broader cultural ideologies of good child care. Culture, communication, and self-development are inextricably intertwined. Culturally distinct communicative practices in which children participate will therefore ultimately lead to different cultural developmental pathways. While traditional research in developmental psychology has focused on mother–child dyads and experimental designs there is an increasing recognition of the need for naturalistic studies of everyday communication with children including their broader social network.

This article addresses culture-based differences in mother–child communication. It gives an overview of studies conducted in various societies across the world and with children at different ages. It aims at pointing to distinct developmental pathways that will evolve from culture-based differences in communicative practices with children. It stresses the importance of studying natural, everyday interactions in which children participate for better understanding the intertwined nature of culture and child development.

Mother–child communication constitutes a central topic in social and behavioral sciences, specifically in developmental research. Communication with children plays a crucial role for cognitive and social-emotional development. Research in the field of psychology has primarily focused on the impact of mother–child communication on socioemotional development/secure attachment (*see* Attachment during Infancy and Early Childhood: Cultural Variations, Development of), language acquisition, and general cognitive development (*see* Biological Preconditions for Language Development; Language Development, Theories of; Language Development: Emergentist Theories; Language Development: Evolutionary Theories; Child-Directed Speech: Influence on Language Development; Theory of Mind during Infancy and Early Childhood Across Cultures, Development of). Communication with children constitutes, however, a much more crucial determinant for child development in that it is the central means to construct social meaning and an understanding of self and self in relation to others. Social interaction with children can be considered the crucial place where development takes place and communication is a central part of this. Culturally different communicative practices in which children participate will hence ultimately lead to different developmental pathways of selfhood and social understanding (*see* Attachment during Infancy and Early Childhood: Cultural Variations, Development of; Joint Attention during Infancy and Early Childhood Across Cultures; Early Emotional Development and Cultural Variability; Self in Culture: Early Development; Values Across Cultures, Development of; Early Memory Development and Cultural Variations; Cognitive Development during Infancy and Early Childhood across Cultures; Memory Development during Infancy and Early Childhood across Cultures; Autobiographical Memory during Early Childhood and Cultural Variations; Concept Formation in Childhood: Cross-Cultural Perspectives; Theory of Mind during Infancy and Early Childhood Across Cultures, Development of).

Mother–Child Communication in Early Infancy

Infants readily engage in communication and social interaction from birth on. Around 2–3 months infants are able to maintain eye-to-eye contact during social interaction and smile to interactional partners more frequently. This in turn allows caregivers to communicate with their infants in more contingent patterns, for example, by initiating turn-taking and interpreting the infant's vocalization and physical movements as meaningful and responding to it accordingly. This pattern has been described as *protoconversation* by Mary C. Bateson (*see* Child-Directed Speech: Influence on Language Development; Language Development, Theories of) and assumed to have a biological component and therefore to show same characteristics in many different languages, such as high voice pitch, exaggerated intonation, slow tempo, repetitiveness, and vowel elongation. The large majority of studies on infant-directed speech/protoconversation was conducted in white, middle-class North American or northern European contexts, that is, within the same sociocultural context of the researchers, and hence might have lead to a methodological artifact that largely ignored culture. The universality of this communicative pattern has meanwhile been challenged and a number of psychological and anthropological studies have found that these communicative patterns are not characteristic for many non-Western cultures (for an overview see Ochs and Schieffelin, 1984; *see* First Language Acquisition, Developmental Psychology of). Extended mock conversations and play dialogues, typical for Western societies, is virtually absent also among the Kaluli of Papua New Guinea and the Samoans of Polynesia (Ochs and Schieffelin, 1984). In cultural societies such as the Gusii in Kenya (LeVine et al., 1994), Kaluli in Papua New Guinea and Western Samoans (Ochs, 1982;

Ochs and Schieffelin, 1984; Schieffelin and Ochs, 1986), or Mayan societies (cf De León, 2000), caregivers do not engage in conversations including dyadic turn-taking with their infants. Mayan Zinacantec babies do however have the status of 'protoaddressees' (De León, 2000), that is, they are addressed with speech in a variety ways, including for instance rhetorical questions, formal address in triadic interaction, speech activities to control the child's behavior. Mayan Zinacantec interactions with children furthermore are characterized to a larger extend by nonverbal communication. Haviland (1998) could show that there is no radical discontinuity between gesture and language in this community and that gestures play a more important role for language acquisition than in Western societies.

First instances of turn-taking have been observed during breast-feeding right after birth (Kaye, 1982; cf Takada, 2011) in that infants stop after having suck for a few seconds, followed by mothers 'jiggling' the infant or breast and the infant resuming sucking. While these findings might suggest some innate and hence universal component of mother–infant interactions, no such pattern was found, for example, among the San in South Africa (Takada, 2011).

Cowley et al. (2004) found that in KwaZulu communities in South Africa the caregiver's actions chime with those of the infant creating an impression of behaving in unison. Often this is highly rhythmic and characterized by frequent vocal overlap or chorusing rather than dyadically following a turn-taking pattern. They suggest to speak of 'protosong' rather than of 'protoconversation' to describe a communicative pattern with infants in this community. Similar findings have been reported by a study among the farming Nso in the Northwester Grassfields of Cameroon (Demuth, 2008).

Also typical communicative patterns with infants in the United States such as engaging and exciting are not common in many other societies. LeVine et al. (1994), for instance, describe that soothing and calming has been the common pattern in infant care among the Gusii, agricultural people in Western Kenya.

French mothers have been found to organize conversational exchanges with their infants in a dyadic form, using mirroring devices, and addressing questions to the child, whereas Senegalese Wolof immigrant mothers were found to include third persons in interactions with their infants and to use more singing and rhyming as well as more imperatives (Rabain-Jamin and Sabeau-Jouannet, 1997).

A study by Gratier (2003) on spontaneous vocal interactions of mothers and their 2–5-month-old infants from India, France, and the United States found both communalities among the three cultural contexts with regard to general rhythmic aspects in the coordination between mother and infant vocalization. On the other hand, the study also revealed significant cultural variability: the Indian mothers produced less space between vocal turns and more overlap of mother and baby vocalizations. They also produced a higher ratio of nonverbal to verbal vocalizations. Moreover, the vocal interaction of immigrant dyads living in the United States showed signs of change in the direction of the host culture.

From an ecocultural perspective, cultural variations in communication with infants can be considered as sociohistorically evolved strategies that are inherently organized by cultural parental beliefs and adaptive to the specific ecocultural pressures and requirements of a given sociocultural environment (Keller, 2007; *see* Ecocultural Theories of Development; Development of Attachment during Infancy and Early Childhood: Cultural Variations). They can be understood as cultural expressions of what might be a basic innate communicative pattern with infants. Besides the caregiver's personality and psychological functioning, therefore communication with children always needs to be understood as serving broader cultural socialization goals (*see* Parenting Attitudes and Beliefs across Cultures). Schieffelin and Ochs (1998) have argued, for instance, that the accommodations to the child reflect a discomfort of Western middle-class mothers with the competence differential between adult and the child and that caregivers use self-lowering (e.g., simplified speech) as well as child-raising strategies (e.g., acting as if the child were more competent than his or her behavior more strictly would indicate) to reduce this competence gap. In some societies, age and status differences can, for example, affect the rights to turns in a conversation (Keating and Egbert, 2004). Among the Gusii, verbal exchange is largely restricted to persons whose kin relationship defines them as social equals. Parents and children, however, are considered inherently unequal even in adulthood and ideally distant as communicative partners (LeVine et al., 1994).

Within attachment theory, for instance the quality of communication with infants during the first years of life has been claimed to have an impact on secure attachment. Mothers who are aware of an infant's signals, accurately interpret them, and promptly respond by showing empathy and insight into the baby's wishes and moods have been claimed to promote secure attachment development in their child. However, these infant care practices correspond to the general Western conception of maternal sensitivity. Good motherhood might be defined differently in various sociocultural groups and other forms of maternal sensitivity and hence communicative practices might similarly lead to secure attachment development (*see* Attachment during Infancy and Early Childhood: Cultural Variations, Development of). According to the Cameroonian Nso beliefs, for instance, a good mother is supposed to know what is good for the child and to decide what is going to be done. There is therefore no 'need' to speculate on what might be going on in the child's mind. Not referring to the internal experience of the child has also been found in other non-Western cultural groups (e.g., Ochs and Schieffelin, 1984). For instance, the Kaluli in Papua New Guinea use little language except for greetings, imperatives, and rhetorical questions toward infants (Ochs and Schieffelin, 1984). This has been related to their belief that infants have no understanding yet and hence are not able to initiate appropriate interactional sequences. Western Samoans have been found to not directly address infants except in the form of songs or rhythmic vocalization (Ochs and Schieffelin, 1984). Moreover, societies such as Samoans (e.g., Ochs, 1982), Kaluli of Papua New Guinea (e.g., Schieffelin and Ochs, 1986), strongly dislike verbal speculation on what someone else might be thinking or feeling or to express personal thoughts also in adult conversations.

Moreover, nonverbal and physical features of communication are equally important, especially in nonliterate cultures (Nsamenang and Lamb, 1994). In this line of argumentation, Gratier (2003) has suggested to broaden the definition of protoconversation to include kinesthetic and tactile modes of interaction and conversational styles that are not centered on the turn-taking format. She states that a protoconversation may also simply consist of conversation without words. Similarly, Ochs and Schieffelin (1984) have proposed that caregiver–infant interactions do not follow a 'biologically designed choreography' (Stern, 1977) but that there are many different choreographies within and across societies.

Mother–Infant Communication as the Cradle of Cultural Meaning

Within the field of psychology, it was Vygotsky (1978) who first argued that social interaction, particularly language, is an important mechanism by which children learn to understand themselves. The sociocultural perspective emphasizes the idea that these interactions are dialogically intertwined with cultural ideologies, which essentially provides individuals with certain frameworks that influence how the individual is seen in relation to others.

The importance of mundane communication for child development becomes clear when looking at communicative practices as locally organized meaning-making processes. It is through reciprocal engagements with others, especially the mother, that infants come to develop a sense of shared experience (termed 'primary intersubjectivity'; Trevarthen, 1998), that is, finding a shared background with another person against which experience can be understood (Hundeide, 1993). By coordinating the mother's intentions with the child's needs and intentions, and interpreting and evaluating the infant's behaviors, both verbally and nonverbally, cultural meaning is dialogically constructed in that mother and infant tacitly negotiate 'contracts' (Hundeide, 1993) of what is acceptable and permissible. Through sharing common experience of what is 'normal' the infant is 'contractually' committed to present (or to position) himself in a certain way as part of the silent agreement of participation. Infant's awareness of reality and learning of culture is hence built through communication with the motives and emotions of other persons (Trevarthen, 1998; *see* Self in Culture: Early Development). As Forrester states: "The desire of any parent for his/her child to be a self expresses itself through culturally specific discourses: language as social action presupposed on the beliefs, narratives and everyday understandings of what is appropriate in context" (1999: p. 42). Through repeated exposure to these 'frames' and ways in which the infant is positioned in the interaction, a relatively stable self-construal, that is, perception of oneself and of oneself in relation to others in the society, is developed. The way the child constructs himself or herself discursively later on in childhood will reflect these relatively stable patterns. A case study on caregiver–infant interactions when the infant was 18–28 months old (Forrester, 2001), for example, could show that the child began to understand and locate herself in the membership categories provided and deemed appropriate within the specific cultural context's and provides insight on how the caregivers' discursive practices facilitated or constrained her emerging conception of what it is to be a self. The sense of self a child acquires hence is in large part determined by the models, metaphors, and constructs of self made available to the child in the discourse surrounding him or her.

There is empirical evidence that children at a very young age display cultural characteristics of conversational patterns and that even as early as at 2 (Gratier, 2003) and 3 (Cowley et al., 2004) months of age, infants already display communicative practices that are conform with the prevailing cultural models of how to relate with their caregivers. Drawing on the microanalysis of a South-African mother–infant interaction, Cowley et al. could demonstrate how a 3-month infant comes to grasp that his mother wants him to fall silent and thus learns to adjust to the expectations of his encultured caregiver (Cowley et al., 2004).

Research with infants from various cultural backgrounds revealed that as early as 6 and even 3 months of age infants' cry melodies show clear differences in the shape and tone of the babies cry melodies.

Mother–Child Communication in Childhood

While cultural ideologies of good child care are largely implicit, they become evident in the different strategies parents in diverse societies use to teach their children to behave well: Inuit parents, for instance, use teasing but would never use shaming or threatening strategies or beat the child (Briggs, 1982, 1998), while frightening and beating are common among the Mfantse in Ghana. However, they would never use shaming strategies publicly (Quinn, 2005). Shaming is, however, common in Taiwanese mothers' socialization strategies (e.g., Miller et al., 2012, 2007) and both, teasing and shaming is common among Kaluli (Papua New Guinea) (Schieffelin, 1986). Teasing was also found to be typically used by Euro-American white working-class mothers but not by Euro-American higher educated white middle-class mothers (Kusserow, 1999; Miller, 1986). Micronesian Ifaluk use anticipative strategies to avoid misbehavior of the child by teaching him or her to be fearful of certain types of ghosts (Lutz, 1988).

The dialogical nature of language acquisition and cultural understanding of the world has been first addressed by the linguistic anthropologists Elinor Ochs and Bambi Schieffelin (e.g., Ochs, 1982; Ochs and Schieffelin, 1984; Schieffelin and Ochs, 1986) within their language socialization paradigm: Through participation in mundane everyday communication, children not merely acquire language but also a cultural understanding of how to make sense of their experience and the world. The focus hence is on how a community's habitus of communicative practices and strategies with children is related to sociocultural orientations (Ochs et al., 2005).

Euro-American middle-class mothers tend to pay more attention to socializing their children into being active conversational partners (Blum-Kulka, 1990; Blum-Kulka and Sheffer, 1993; Junefelt and Tulviste, 1997), and to praise their children, fostering assertiveness, cognitive development, and stressing the child's individuality (e.g., Junefelt and Tulviste, 1997).

Mother–Child Coconstructions of Autobiographical Narratives

As infants become language-using toddlers, parents begin to engage in talk about past and future events with them. Children on their part start to tell stories of personal experience in interactions with others in the second or third year of their lives. A number of studies have therefore addressed the relation between mother–child communication and the development of autobiographical remembering and storytelling (see, e.g., Nelson and Fivush, 2004 for an overview). Self-narratives can be considered to have a crucial function for identity-formation and self-construal (Bruner, 1990). Through repeated participation in communication with caregivers children learn how to tell stories about themselves in culturally appropriate ways and have internalized what constitutes a 'good story' that is in line with broader cultural ideologies. By participating in these practices, children not only acquire cognitive skills like telling a story but most of all they learn to make sense of the world and of themselves – they acquire cultural tools to develop identities, affective stances, values, and moral orientations that are in line with broader cultural ideologies of a community (e.g., Miller et al., 2007). Learning to engage in storytelling hence is inseparably bound to cultural ways of constructing a sense of self.

Cross-Cultural and Quasi-Experimental Studies

A number of quasi-experimental studies have found cultural differences in the way mothers coconstruct stories about past events in elicited interaction with their children as well as differences in how children on their part tell stories about their experience (*see* Autobiographical Memory during Early Childhood and Cultural Variations). Mainly, these differences have been related to different cultural self-construals and differences in the emphasis of the dimensions independence and interdependence or autonomy and interpersonal relatedness. Mothers from different cultural contexts may have different goals regarding the purpose of remembering, and these goals further influence the way in which they speak to their children.

Euro-American mothers, for instance, have been found to use a high-elaborative child-centered conversation style that has been shown to be associated with their values regarding an autonomous, individual identity (Wang, 2007). Euro-American children on their part produce detailed autobiographical narratives and independent self-construals. Chinese mothers tend to use a more didactic, mother-centered approach, focusing on appropriate behaviors, rules, and social obligations which has been shown to be associated with confucian thinking and their values regarding interdependence (e.g., Wang, 2006, 2007, 2008). Chinese children on their part show greater orientation toward social engagement, greater concern with moral correctness and authority, less autonomous orientation, more expressions of emotions, and more situational details in their accounts compared with their US counterparts.

Mothers in highly educated Western urban middle-class societies (defined as autonomous context) have been found to adopt an elaborative-evaluative reminiscing style and person-oriented approach in their conversations with toddlers, whereas mothers from non-Western subsistence-based communities (defined as relatedness context) have been found to adopt a repetitive reminiscing style. Children in the prototypical autonomous contexts accordingly showed a highly elaborated style in narrating autobiographical memories whereas children in the prototypical relatedness context provide low elaboration in their autobiographical accounts (Schröder et al., 2013; Tõugu et al., 2011, 2012).

A number of studies have investigated mother–child communication during family mealtime interactions in different cultural communities. Blum-Kulka (1990, 1997) found that American mothers of schoolchildren paid considerably more attention to following conversational norms and turn-taking at the dinner table than mothers from Israel. Euro-American mothers have been found to praise their children more often than Estonian and Swedish mothers whereas Estonian mothers have been found to use more regulation than Euro-American and Swedish mothers (Junefelt and Tulviste, 1997). Finno-Ugric societies have been found to generally talk less and accordingly also talk less with their children (Tulviste, 2004b). Estonian mothers have, however, been found to use a highly directive conversational style with a high proportion of imperatives (Tulviste, 2004a; Tulviste et al., 2004) compared to Finnish, Swedish, and Latvian mothers.

Discursive Practice Approach

While most of the above studies have been conducted within a traditional experimental design and/or within a (post)positivistic research paradigm that conceives of language as referential, there is an increasing number of researchers who point to the constitutive role of language and conceive of language as action in its own right. These approaches are based on social constructionism and Wittgensteinian psychology and closely linked to discursive psychology (e.g., Edwards and Potter, 1992; Shotter, 1993). They take a 'communicative' or 'discursive' practice approach in that they privilege the sequential microanalysis of 'talk-in-interaction,' that is, of what is being done with verbal and nonverbal communications in the way an interaction develops. They allow for a more comprehensive cultural analysis because cultural orientations are expressed not only in the content of talk but also in the way that discourse is organized, enacted, and embedded (Miller and Fung, 2012).

A classic ethnographic study on children's personal stories was conducted by Heath (1983) who compared working-class families of a European-American community and a neighboring African-American community in the Piedmont Carolinas. While children's stories in the European-American community adhered to a criterion of literal truth and focused on children's weakness or foolishness, the stories of the African-American children adhered to fictional embellishment and focused on aggrandizement of the protagonists.

The work by Miller et al. (2007) found that Taiwanese mothers typically use storytelling as a didactic medium to invoke moral and social rules in order to correct children's misbehavior while US middle-class mothers typically

downplayed their children's misdeeds in conarrated stories in order to not threaten the child's self-esteem.

In a study on middle-class family interactions in Los Angeles and Rome, Fasulo et al. (2007) examined conversational practices between parents and children with regard to everyday hygiene and household cleaning tasks that foster familial and cultural values such as autonomy, interdependence, and responsibility. Their findings revealed differences in the style and amount of parental control over cleaning tasks, and the number of options given to children in the process and sequence of tasks, which may lead to the construction or limitation of children's agency.

Sirota (2006) could show how mother–child bedtime routines in US middle-class families serve as an interactional matrix to foster autonomous self-initiative in tandem with a growing capacity for relational communion with others.

Swedish mothers have been found to follow egalitarian communication patterns with their children that are in line with a general orientation toward democracy and equality (Aronsson and Cekaite, 2011). Swedish children on their part have been found to be more active in controlling their mothers' behavior compared to Estonian and Finnish children, possibly illustrating the Swedish value of generational equality (Tulviste et al., 2004).

By comparing Italian and Euro-American family dinner interactions, Ochs et al. (1996) could show that children's attitudes toward food (as pleasure vs as reward) are socialized through discursive practices by caregivers.

A study on Italian family dinner interactions by Sterponi (2009) could show how parents scaffold children's participation in episodes of accountability through vicarious accounts that serve as face saving acts both for the child whose action was signaled as improper and for the parent who initially requested the account.

Methodological Considerations and Future Directions

Understanding child development in cultural context has become a central concern in developmental psychology in recent years. More and more scholars acknowledge that there are multiple developmental pathways and not a single universal pathway of healthy development (e.g., Keller, 2007). Understanding child development in cultural context requires attention to meaning – more precisely meaning-making processes in social interactions (Miller and Fung, 2012). Specific attention hence needs to be given to communicative practices in which children participate.

Traditionally, psychological research on communication with children has focused on the mother–child dyads whereas in the majority world children participate in multiparty interactions (De León, 2012). Most studies have been conducted in experimental or relatively controlled designs. Language in these approaches has primarily been treated as referential.

A discursive practice approach that conceives of language as constitutive, however, calls for methodological approaches that are able to capture the intertwined nature of culture and development in mundane everyday interactions and naturally occurring communication. This implies the broader social network of children such as fathers, siblings, peers, neighbors, and extended family. Research designs that combine ethnographic procedures with microanalytic conversation and discourse analysis have proven to be very fruitful in this field (Ochs and Schieffelin, 1984; Miller and Fung, 2012; Demuth and Fatigante, 2012).

A discursive practice approach that solely focuses on verbal communication risks, however, to neglect embodied language practices through which children constitute their social world in the midst of moment-to-moment interaction. It is therefore crucial to include gesture, mimic, and other nonverbal aspects of communication. There is also an increasing acknowledgment of the importance of the phenomenological immediacy of experience in discursive practice approaches that is central to embodied action (Cresswell and Teucher, 2011).

Furthermore, research needs to consider the sociocultural embeddedness of communicative practices with children, for example, ways in which a community's habitus may influence the communicative practices with children. In this line of argumentation, Ochs et al. (2005) suggest a model of Child-Directed Communication that extends caregiver–child communication to semiotic resources beyond speech.

In order to avoid the bias of generalizing from studies with white Western middle-class families more research with participants from understudied non-Western societies, as well as with working-class samples are urgently needed.

Finally, developmental research needs to take into account children's active participation in their social worlds (*see* Qualitative Methodology in Developmental Psychology). Children are not passive participants of cultural practices but actively contribute to the coconstruction process of social interaction.

Motherhood

Karen J Swift, York University, Toronto, ON, Canada

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article traces ideas and ideologies of motherhood from prehistoric times through the present. Motherhood as a dominant discourse for personal, social, and state purposes is explored. The actual experience of motherhood by women historically and in different parts of the world is discussed. The policing and control of motherhood in various ways, by males, families, religions, and the state, are examined. Some ideas of the future of motherhood by various authors are presented, and the author shows how mothers themselves increasingly shape motherhood.

Introduction

The idea of motherhood has occupied iconic status historically and in cultures around the world. This article addresses myths, discourses, experiences, and realities of motherhood, primarily, but not only, in the West. The author concludes with ideas about the possible future of motherhood.

Images and Myths of Motherhood

According to Thurer (1994), the oldest of all gods was the Great Mother, who was believed to be all powerful. The role of mothers from the Paleolithic era and for many centuries forward was highly valued and celebrated. Only females could reproduce the human species and only mothers could be identified with certainty as the biological parent of a child. The continuation of humanity and family line depended upon mothers, who were strongly associated with the earth as the source of all life.

Adrienne Rich (1976), too, cites motherhood in prehistory as a site of power, although becoming constrained even then. Early on, women were associated with nature, as denoted by the phrase 'mother earth.' Nature was seen as woman's domain, the source of her powers of reproduction, and as the symbolic representation of her fecundity. Images of early mothers were often in the shape of vessels. The tree in leaf was a female representation of the transformation of life and of the dependency of new life upon the life-giving source, the mother. Even ancient tombs were designed to represent the mother, with labyrinthine forms suggesting female internal anatomy and representing the rebirth of the human spirit. These associations project motherhood as a natural fact, as instinctual, as inevitable for women to aspire to and accomplish.

In ancient Egypt, the goddess Isis was considered the paragon of motherhood, a patron goddess of childbirth and a figure of both gentle motherhood and confident queenhood. In Africa, a common symbol of motherhood is the creation goddess associated with the moon and water. The creation goddess nurtures and has power over life. In Hinduism, Devi Ma is the Mother Goddess; she is not only a creator but also a warrior and destroyer. Buddhism has its roots in the Great Mother Tradition. In Christian tradition, Eve, the first mother, is depicted as both sinful in giving Adam the poisoned apple and an enduring symbol of creation, the 'Mother of all the living.' In the Jewish faith, Adam's partner in the Garden of Eden is Chavah, who embodies the essence of life and ability to create new life, nurture, and enhance new life. Unlike Eve, Chavah is a thoroughly positive figure. Mary is the mother of Jesus, conceived through a (sexless) miracle and worshipped by many Christians today. She is portrayed as all giving, all loving, and all sacrificing and remains as an iconic image of the ideal mother. Hence, in ancient times, men were secondary to women because of women's powers of reproduction.

However, for most if not all of the major religions, these early female and motherhood symbols eventually gave way to male leaders and gods in power and authority. According to Campbell, the prodigious power of motherhood in the earliest stages of human history eventually encouraged in males the desire to "break, control and employ [that power] to its own ends" (1972: p. 372), a shift he identifies as beginning about 30 000 years BC. Thus, depiction of the divine began to change from female to male figures and symbols. Most religions have special roles and rules for women, including mothers, that place them as institutionally less powerful than men. Symbolic figures glorifying motherhood, although still important to these various religions and cultures, have long since ceased to reflect the immense power that women as creators of life once held.

Engels (1942), in his famous study of the origins of the family, concurs that prior to recorded history women occupied positions of status and power, never since reproduced. He has traced the development of the monogamous family, noting the earlier importance of mother-right based on the reality that until monogamy was established and enforced only mothers could be identified with certainty as a biological parent. Father-right becomes the norm with monogamy in marriage, monogamy that is for women, along with inheritance rights for fathers through laws establishing that the husband is the father. The association of motherhood with earth, oceans, transformation, growth, and nature became, as patriarchy developed, less associated with power and increasingly with symbolism of woman as nurturers of the young produced through childbirth, and as molders of the unformed children who in turn were increasingly viewed as potential heirs, nurtured by the mother but owned and controlled by the father.

Motherhood as Ideology

Understandings of motherhood arrive in contemporary times as a set of discourses found in everyday conversation, news, law, and policy. Two closely related strands of discourse are easily identified. The dominant discourse of motherhood has remained stable through several centuries; motherhood is viewed as the main purpose in life of every woman and the most illustrious of states. Through much of recorded history, and guided by patriarchal forms of thought, law, and discourse, motherhood has been presented as women's ultimate purpose and main mission in life, to be a holy mission and the highest form of service to humanity.

A well-known summary of the ideology of motherhood is the "belief that all women need to be mothers, all mothers need their children and all children need their mothers" (Oakley, 1986: p. 67). Many feminists have examined the 'cult of motherhood' as an all-encompassing mixture of a biological imperative to reproduce and a social imperative for mothers to provide stabilizing and moral influences for children and society at large. As the mother came to be cast as the all-important figure for the child, belief held that she should devote herself body, mind, heart, and soul to the enterprise of caring for that child. The 'bliss' of motherhood was promoted, not least by the Christian church, as the highest calling for women. An extension of that calling is that the mother–child bond is sacrosanct and must extend into the life of the child in the form of primary care by the mother throughout the child's life. Western feminists point out that the glorification of motherhood actually serves as a method of constraint; 'proper' mothering dictated by ideology demands that mothers stay at home and spend most of their time taking care of children and creating a comfortable, stable home atmosphere.

A related discourse of motherhood follows from the state's interest in controlling and using female fertility for nation building and economic purposes. Yeo (2005) states that motherhood in this sense was 'created' around the middle of the eighteenth century. The developing discourse of motherhood in Europe after that period tasked mothers not only with responsibility for continuation of the family, the production of (male) heirs, and the improvement of class position for the family but also for purity of the race (white). Thus, motherhood came to be not only a private matter but also a matter of importance to the state, which it remains. Consequently, when population growth is needed, policies are developed to encourage women to become mothers. In times of overpopulation or when poor or racialized mothers are deemed to be overproducing children, policies supporting child care and access to health care are likely to shrink. Malthus, writing two centuries ago, instructed that only families who could support children should reproduce. Otherwise, he thought, their children 'must starve' (Malthus, 1803: p. 226). Yeo (2005) claims one of the 'master narratives' governing European motherhood in earlier centuries was that of nation building, especially in the colonies. The creation of new nations required a growing, healthy population, with women's roles focused on producing and rearing soldiers and laborers. Once nation-building efforts became established, mothers were called upon to contribute to the development of a large and prosperous white middle class needed to perpetuate and grow capitalism. For this purpose, white mothers were needed to learn, teach, and demonstrate the moral authority the middle class required to dominate those below in the social, economic, and racial hierarchies. These efforts have produced an intersection of class, gender, and race that carries over into the current century in the West.

The development and growth of the middle class coincided with the expansion of industrialization in both Europe and North America. Beginning in the nineteenth century, increasing industrialization brought large numbers of men into the new industrial labor force, creating a gendered separation of men and women in their daily and working lives. Women were increasingly denied entry into the public world of paid work and discourse (Fegan, 1994). According to many white feminists, it is in this period that the 'cult of motherhood' was intensified in the West. The new jobs were for men, hence the 'living wage' argument: if men could earn enough in the paid labor force to support wife and children, women could then leave paid jobs to men and do their biological and social reproductive work in the home.

A contemporary extension of this 'state-based' discourse of motherhood is generally attributed to Adrienne Rich (1976), who famously identified two meanings of motherhood. One is the relationship of a woman to reproduction of the species and children. The other is the 'institution' of motherhood, which Rich names as male controlled and a product of patriarchy. This ideology of motherhood is called upon to inscribe upon women motherhood not only as instinct and selflessness, but also as subordination to others, namely, men, in the interests of carrying out their motherly duties. The institution of motherhood, anywhere in the world sends messages about how to feel, think, and act as a mother.

For women of color, however, the ideology of motherhood portrayed by white feminists does not fit so well. Collins (1994) argues that patriarchy and male domination have not historically been the primary forces controlling the shape and form of motherhood for women of color. Nor do the dichotomies presented by white feminists – public/private, male/female – apply in the same ideological way. For many women of color, experiences of motherhood involve survival issues, for their children, for themselves, and for the group. The isolation of the mother in the private home is a distant dream for these mothers. Instead, they, their children, and their male partners as well, may all have carried out paid work together, in fields, as migrant workers, doing piecework, as guest workers in foreign countries. Some, for instance, Aboriginal mothers, have not been allowed to perform their mothering work for long periods, as their children have been forcibly removed to residential schools for lengthy periods. The nuclear family, with the clear divisions of labor noted by white feminists, is often not their family form. This can be the case for white families as well. In these, the extended family may prevail, meaning the work of mothering goes on into succeeding generations. Many of these mothers perform their mothering work for other women's children, as they leave their own behind in other neighborhoods or other countries to care for children of better-off mothers. Collins (1994) argues that for women of color, the state has harnessed motherhood for its own purposes of producing and controlling cheap labor in support of elite

populations. While Collins' argument holds for many women of color, these mothers also experience patriarchy as a driving force in their lives. In their roles as paid laborers, colonial relations may rule their mothering, but when they return home, it is male rule they must endure.

For childless women, the discourse of motherhood as life's purpose for every woman is also ill-fitting, posing problems of identity and social value for childless women. If motherhood is the main justification of life for women, and that purpose remains unfulfilled, who are they and what social status and value can they have? The shame of barren and single women applies in most cultures and throughout history. Images of the maiden aunt, the old maid, or the spinster come to mind. One socially legitimate and often revered role for single women has been the religious life (Yeo, 1999: p. 208). In the late nineteenth and early twentieth centuries, the idea of the 'social mother' was invented (Yeo, 1999: p. 209), largely by social workers, as another way of providing a role for childless women. Social mothers may not have had their own children but they performed a motherly role in the community. Social work itself as well as teaching, nursing, and related 'women's professions' to some extent grew out of this idea. Of course, this direction was a double-edged sword for women entering the new professions; it allowed them entry into the public world of paid employment, but it restricted them to interaction mainly with other women and children and to very low paid work (Yeo, 1999).

Thus, ideologies of motherhood serve state, social, patriarchal, and personal purposes. While there is a central and glorified ideology of motherhood that pressures and exhorts women to perform their lives and their mothering role in certain ways, the experiences of motherhood for different groups of women invariably fail to conform to the ideal.

Policing Motherhood

In spite of the ideological glorification of motherhood in discourse, symbols, and myths, many authors have indicated that the actual experience of motherhood over past centuries has been less than glorious. For centuries, motherhood was a life-threatening condition, as many women died in childbirth. Throughout the twentieth century, European and North American women were denied effective forms of birth control and safe abortions that could save them not only from the health hazards of childbirth, but also from the hazards of raising too many children on small incomes. Margaret Sanger titled her 1928 book *Motherhood in Bondage*, including in it the pleas of thousands of overburdened, often unhealthy mothers for access to the new forms of birth control.

The threat of unsafe childbirth remains for many women in poor countries. Maternal death rates remain high, for instance, in Asia and Africa, where about 95% of the world's maternal deaths occur; 1 in 16 women die in childbirth in Sub-Saharan Africa as opposed to 1 in 2800 in 'developed' regions. For every woman who dies, two or three dozen others incur disabling injuries through childbirth. And should they survive to raise their children, most mothers in these regions will know poverty and malnutrition for both herself and her children, and will likely experience the deaths of one or more of her children before the age of 5 years (Rosenfield et al., 2007).

As many women realize, motherhood generally involves hard work and considerable sacrifice, and the central guiding ideology of motherhood produces social norms and expectations that can be utilized to judge mothers' performances regardless of the socially constructed difficulties they face. Should they balk, or depart from the norms set by the state and society, a variety of laws and policies are available to police motherhood for state and social interests. In China, the government imposes a limit on number of children for certain families, mainly in urban areas. After that, the state can impose fines or even involuntary abortion and/or sterilization. In other places, organized religion imposes strict rules for motherhood, quite often policed by the men of the family, religious institutions, and/or the state.

In the West, motherhood has for some decades been policed by a 'science' of correct ideas and behaviors, along with state and religious controls. Scientific motherhood is several centuries old, stimulated by Enlightenment ideas of the existence of scientific, albeit frequently revised, 'facts' and 'truths' alongside the development of professions with relevant expertise. Physicians authored some of the earliest advice, thus beginning the medicalization of motherhood. Early examples of advice to mothers are William Cadogan's 1749 *Essay upon Nursing* and William Buchan's (1784) *Domestic Medicine*, in which he instructed that "nothing can be more preposterous than a mother who thinks it below her to take care of her own child" (p. 28); and J.C. Ryle's scripture-inspired advice that children should be trained "in the way they should go, and not in the way that they would" (1888).

Advice literature presumes a conception of childhood, new in the eighteenth century, as a stage distinct from adulthood, and a new idea of motherhood, requiring women to follow the proffered advice. As advice has changed over the centuries, so have the underlying notions of motherhood and mothering required to follow it.

Another source of advice comes via the education system. Frederich Froebel, for example, encouraged a system of learning through play, to be taught to parents (mothers) and carried out in the home. His work began in the mid-nineteenth century and continues to influence education and parents. Some years after Froebel, Jean Piaget developed his theory of children's cognitive learning patterns and development, a theory that remains infused in ideas of proper parenting as a path to optimal childhood development. Freud's theory of the Oedipus complex, involving desire for the mother by both male and female children, later contributed to ideas of failed motherhood as the central feature in the developmental problems of children. Many psychologists considered the mother as outright dangerous. Thus, motherhood was not celebrated but rather denigrated as the source of virtually all childhood problems. John Bowlby followed Freud's psychology with now famous concepts about attachment and bonding. Bowlby's work suggested that only biological mothers could properly bond with children, thereby reinforcing notions of the ever-present doting mother as necessary for healthy childhood development. This work has been much criticized by feminists, but remains influential in mainstream ideas of good mothering.

Building on Freudian psychology in the postwar Western world were the burgeoning sciences of psychology and psychiatry. In this period, mother-blaming was at its height, and a deepening binary emerged: mothers as saints, as promoted through the traditional ideology of motherhood, and mothers as villains, as discovered through science. In the United States, the postwar literature emerged tying motherhood to a crisis of manhood and masculinity. Mothers should not be too warm, too affectionate, or too close to their sons, for fear of producing an emasculated adult. Motherhood was even linked to national security, to the growing 'menace' of communism, and fascism – "Naziism was … a mom surrogate with a swastika for a heart" said the psychiatrist Edward Strecker (cited in Aidenbaum, 2006). Meanwhile, experts in the social and psychiatric sciences blamed mothers for a raft of mental health issues – neuroses, depression, repression, insecurities of all kinds, delinquency, and homosexuality. One 1985 study (Caplan and Hall-McCorquodale) reviewing dozens of published clinical studies found that regardless of the problem, the large majority of research studies examined the mother–child relationship as a problem source, and about two-thirds of the studies blamed the mother's 'pathology' for problems that included everything from 'mental handicaps' to colitis. Second-wave feminist Betty Friedan commented that the mother could be blamed for almost anything. Freudian psychology has been critiqued and much of it dispensed with, but the discourse of dangerous mothering has not disappeared but has become lodged in laws controlling female bodies and welfare state provisions.

Laws and rules governing the female body and its reproductive capacities were institutionally established as early as 1803 in Great Britain with the passage of The Ellenborough Act, which provided the death penalty for abortions occurring after 'quickening.' Laws criminalizing abortion followed in Canada, focusing on criminalizing abortionists. Shortly after Confederation in Canada, abortion laws were extended to criminalize the woman herself. Access to birth control in these countries was tightly controlled by law into the twentieth century, resulting in enforced motherhood. While these laws have been loosened in many parts of the world, control of the reproductive capacities of women continues, for example, through American policy denying foreign aid to programs that include abortion (Blanchfield, 2013). Similarly, Canada does not fund abortion through foreign aid, and allocates only a very small portion of its aid budget to family planning (Clark, 2010). Law and policy allowing legal abortion are regularly challenged by lobby groups and politicians in the English-speaking world and elsewhere.

In contrast, policing motherhood occurs across the world, and policies enacted to prohibit motherhood for some women. The United States had a forced sterilization program, generally applying to women and immigrants, in the early 1900s, in an attempt to purify the gene pool and produce a society without social problems (Webster University, n.d.). The United States Supreme Court of the era upheld state laws allowing involuntary sterilization, including for intellectually disabled people and some immigrants. The not so hidden message was that motherhood should not be experienced by all women but by those socially selected for specific reasons. In Canada, Sweden, Japan, Germany, and elsewhere in the first half of the twentieth century, forced sterilization occurred for eugenic reasons (Webster University, n.d.). Sometimes, population control is the purpose, as in contemporary China, or gender control through selective abortion and/or infanticide, that occur in communities that do not value girls. Selective abortion can take place in countries that have relatively open abortion policies.

The modern welfare state has been built on the foundation of Elizabethan Poor Law, which distinguished the deserving from the undeserving poor. The original laws viewed vagrants as the undeserving, but low-income, single, and young mothers have long since served as the centerpiece of the undeserving population (Abramowitz, 1989). Thus, motherhood is classed as well as raced. The middle class, the married, and the white are generally viewed as more deserving, and are socially placed so that help from the state is not so often needed; when it is, they fare no better than the single, the poor, and those of color.

Child protection services, originating in the West in the last decades of the nineteenth century, continued the deserving/undeserving distinction, and generally created with urban, poor, and often racialized mothers (and their children) as their target group – 'bad mothers' (Swift, 1995). In the beginning, these examples of unsuccessful motherhood were most frequently charged with neglect of their children. Neglect could mean leaving children unsupervised or failing to provide adequate food, clothing, shelter, education, health care, and discipline. Neglect, although legally aimed at parents, virtually always means mothers, usually poor mothers, who often have no means of providing sufficiently for children. From the beginning, the most stringent punishment for failed motherhood has been removal of the children from the mother's care. Recently, the phrase 'failure to protect' has become embedded in child protection law usually to mean failure to protect children from witnessing violence perpetrated against the mother by a male, often the children's father. Although not articulated, an ideal of motherhood haunts the law, and failure implies transgressing a standard. Contemporary child welfare practice has further encoded such standards in assessment tools, notably risk assessments, which purport to measure numerically the risk that a child will experience bad mothering at some future point (Swift and Callahan, 2009).

Clearly, ideas about ideal motherhood remain firmly entrenched in child protection law. Davies and Krane (1997) argue that mother-blame, still based on an unspoken idealization of the nurturing capacities of all mothers, permeates child protection work. They also point out that the actual work of mothering is invisible in the process of evaluating the accomplishments and failures of mothers who come into contact with child protection services. Mothers caught up in the system are sent to parenting classes to learn the skills and attributes of the good mother; anger management courses to learn self-control; drug rehabilitation to become sober, all to conform more closely to ideal motherhood.

Institutional child welfare plays a central role in reinforcing the dominant ideology of motherhood by regularly producing exemplars of 'bad mothering.' Child welfare services also legitimize scientific mothering, through their use of expert prescriptions to mothers. These prescriptions will not be

contained in the West. The United Nations Convention on the Rights of the Child, developed in a spirit of improving the life circumstances of the world's children, asks developing countries to create institutional structures for child protection (UNICEF, 2013). These countries, under pressure to conform to the Convention, reach out for Western models of child protection. As they do, the invisible, unspoken ideal of Western motherhood may become more entrenched around the world (Swift and Kikulwe, 2012).

The Future of Motherhood

In Marge Piercy's (1976) futuristic novel *Woman at the Edge of Time*, motherhood as a gendered role and activity no longer exists. Children are conceived in laboratories through random selection of genetic attributes, raised to viability in artificial wombs, and cared for after birth by groups of three comothers, some of whom may be male. Every child is a wanted child, and all infants and toddlers are housed together in large nurseries.

This vision of the future is not far-fetched, considering scientific advances in fertility. Work on developing an artificial uterus is underway. Scientists are constructing human sperm, eggs, and wombs in the laboratory, and cloning animals was successfully achieved years ago. Ethical considerations currently prevent science from taking these advances to an end result of producing an artificially bred human being. Margaret Atwood (1985) overcomes this problem in her fictional story of women in *A Handmaid's Tale* where a country founded under racist, theocratic, and military rule keeps a class of women as concubines (handmaids) for reproductive purposes in an era of declining births. Handmaids are paired with upper-class males for reproductive purposes, and their offspring given to mothers of the proper class to raise.

One vision explores what it might be like to do away with biological motherhood; the other examines a world that utterly controls motherhood for state and class purposes. Although extreme, each portrayal emphasizes potential directions for the future of motherhood and mothering, which may or may not appeal.

In the contemporary West, motherhood is a personal choice, owing to effective, accessible forms of birth control and safe abortion and feminist challenges to the 'institution' of motherhood. Western women are choosing later motherhood and fewer children than in the past, and combine motherhood with paid labor. Most mothers in these societies have achieved a level of personal liberation and choice undreamt of a century ago. Current discourse speaks of parenting, which often means mothering, but increasingly involves fathers. Various state-supported programs and policies such as income support, maternity/paternity leave, and subsidized child care centers, while far from perfect, facilitate increased personal choice and assistance with child rearing. Motherhood is not exactly as it used to be, and many are thankful for that. Nonetheless, in the West, mothers continue to struggle for control of their own bodies through ongoing political threats to legal abortion; and programs such as child care that support tasks ordinarily undertaken by mothers but that are now shrinking under neoliberal policies attacking the welfare state.

In the Global South, things are different. With high rates of maternal death in childbirth, the AIDS epidemic, poverty for the majority, armed conflict, and state instability, motherhood remains a risky business. Coupled with these problems, a recent report (United Nations Population Fund, 2012) reveals that 222 million girls and women in developing countries are unable to access appropriate and timely 'family planning' assistance, including contraceptives, which the United Nations now considers a basic human right. Few women in these regions can control their own fertility, and the motherhood that follows is often not a personal choice, thereby reconstructing a world of deserving and undeserving mothers.

Mothers around the world simultaneously seek to extend the conditions and roles of motherhood in courageous and world-changing ways (O'Reilly, 2011). In South America, motherhood has been successfully employed as a political strategy in human rights struggles. The Mothers of the Plaza de Mayo demonstrated for many months in the 1970s, challenging the Argentinian government, along with that of the United States, to account for their 'disappeared' children, all probably dead. This struggle began with individual mothers seeking information about their children's fates and developed into a powerful ideological weapon against the state, which was reluctant to use force against mothers. Chilean mothers used a similar strategy for political and personal ends against the Pinochet dictatorship in the same decade, using their role as nurturing mothers as a powerful challenge to the government's savagery. Both groups reconstructed the notion of motherhood in the process, from one of an apolitical home-bound servant to one of active agents in the political sphere.

These examples of advocacy are models for many other groups of mothers wanting to challenge violent states, including the Mourning Mothers of Iran, demanding accountability for the deaths and disappearances of their children; the Mothers of Acari, who opposed political violence in Brazil; and Russian mothers fighting to expose and end human rights abuses in the military.

Women in Ireland, many of them mothers, have marched to end the violent 'Troubles' between North and South. Mothers from Israel and Palestine have reached across borders to seek peaceful solutions to the ongoing conflict in the Middle East. Mothers in countries around the world work on environmental issues, some winning prizes for their efforts. Other mothers-led groups promoted maternal values of nurturing and cooperation to promote a less violent world. Examples are Mothers Against Human Trafficking; PeaceXPeace, a group promoting sustainable world peace; Mothers Against Drunk Driving; and many groups opposing gun violence. Mothers in Africa and other low-income regions are rapidly moving into the world of breadwinning, developing small businesses, with the aid of microloans, to support their families and communities (Kristoff and WuDunn, 2009; Microcredit Summit Campaign, n.d.). Efforts to contain motherhood, order its boundaries and activities, and confine mothers to traditionally prescribed activities are weakening. Motherhood is increasingly being shaped by mothers themselves, in the interests not only of their own children but also those of the public and political worlds.

Abstract

Traditionally, research on motivation and action has focused on the role of motives and needs, but also on expectations, attributions, and control beliefs. Nowadays, when it comes to answering the question of how motivation relates to action, research includes the concept of goals. But pursuing goals with the right content and structure in the proper situational context does not yet guarantee effective goal attainment. People often have to engage in self-regulatory thought to further their goal pursuits. In this article, we review the history and current research associated with these three broad perspectives on motivation and action.

Traditionally, research on motivation and action has focused on the role of motives and needs, but also on expectations, attributions, and control beliefs. McClelland (1985) distinguished three basic groups of motives: the achievement motive, the power motive, and the affiliation motive. As food is the reward or incentive for hunger, so is improving one's performance on a given task the incentive for the achievement motive. The incentive of the power motive is having impact, control, or influence over another person, a group, or the world at large. Finally, the incentives for the affiliation motive extend to sexual pleasures (sexual motive); being together with people (need for affiliation); and experiencing harmony, concern, and commitment (intimacy motive). All of these motives may entail a hope for success and a fear of failure component. Trying to meet a standard of excellence may not be triggered solely by hope for success, but also by fear of failure, and spending one's spare time affiliating with others may not be determined solely by the anticipated positive feelings of togetherness, but also by fear of rejection.

In principle, all humans are assumed to share these various motives, although with different strengths. Motive strength can be assessed by exploring both the array of situations a person interprets in terms of a given motive (e.g., a person high in need for power interprets all kinds of situations as power related) and the intensity of the anticipated affect associated with having acquired respective incentives. Commonly this is assessed with the Thematic Apperception Test, which contains pictures of scenes loosely related to the motives measured.

Recent research has linked the activation of different motives to different hormonal responses that in turn facilitate motive-specific behaviors. Scoring high on a certain motive implies a recurrent concern for acquiring the respective incentives. For instance, people high on the affiliation motive perform affiliative acts frequently and energetically, readily perceive affiliative cues in the environment, and quickly detect affiliative networks. Also, predictions of the professional success of managers are strikingly accurate, particularly if one considers the motive dispositions in achievement (high), power (high), and affiliation (low) in concert.

However, attempts to predict behaviors from motives commonly fail when engagement in these behaviors is based on conscious reflection. When it comes to choosing between courses of action or tasks of different difficulty, or to persisting on a given task versus leaving the field, people deliberate on the feasibility and desirability of the alternative courses of action.

One of the first attempts to integrate cognitive aspects of motivation was made by Atkinson (1957) in his risk-taking model. He proposed that the subjective probability of success and the task's perceived incentive value conjointly affect task choice, both variables being influenced by the perceived difficulty of the task. Whereas easy tasks lead to a high subjective probability of success (direct function), they also possess low incentive value (inverse function) because the anticipated affect associated with success (pride) is the lowest for easy tasks. The reverse is assumed for difficult tasks. Atkinson suggested that multiplying probability of success and incentive value will give a good estimate of whether a person will choose to work on a task, especially when the obtained score is weighted by the approach (hope for success) and avoidance (fear of failure) components of the person's achievement motive.

Elaborations of the Atkinson model (e.g., Heckhausen, 1991) added further expectation-related concepts (e.g., the expectation that successful task performance will lead to the anticipated incentives) and differentiated various incentives (e.g., extrinsic side effects, such as when an achievement task has affiliative benefits). Atkinson's model has also been elaborated by attribution theorists (Weiner, 1992) who attempted to understand changes in expectations and incentive value in terms of the attributions made for past performances. Moreover, Weiner discovered that the approach component of the achievement motive (hope for success) is associated with attributing failure to luck or lack of effort and success to ability, whereas the avoidance component is linked to attributing failure to lack of ability and success to luck.

Recognition of the motivational importance of expectations and attributions was the starting point of the cognitive revolution in the psychology of motivation that also introduced the concept of control beliefs. Self-efficacious individuals hold the firm belief that they possess the potential to execute the kinds of behaviors that a given task demands (Bandura, 1997). People acquire this belief by reflecting on their own relevant past behaviors, observing the behaviors of similar others, being evaluated by significant others (e.g., teachers), and observing their own physiological reactions when challenged by a given

task. High self-efficacy beliefs are associated with choosing aspiring goals, exerting strong efforts to attain these goals, and persisting in the face of obstacles and hindrances.

The Concept of Goals

Nowadays, when it comes to answering the question of how motivation relates to action, research relies upon the concept of goals. In our opinion, the concept of goals helps the cognitive explication of a person's readiness to make a certain response and to execute it in an energized manner. Importantly in this regard, Ajzen (1991) suggested that this readiness should be assessed in terms of a person's intention to make the response. Such intentions can be conceived as self-imposed or assigned goals that imply standards that the person intends to meet (with respect to quality and quantity criteria). Doing so allows asking new questions such as, what makes people reach their goals and what makes them fail to do so?

Determinants of Effective Goal Pursuit

Goal content strongly affects the chances of attaining a goal. For instance, Ryan et al. (1996) have argued that goals of autonomy, competence, and social integration favor creativity, cognitive flexibility, deep processing of information, and effective coping with failure. These effects are assumed to be mediated by an intrinsic self-regulation, as the needs of autonomy, competence, and social integration are associated with intrinsic goal striving in line with a person's interests or core values, rather than with extrinsic goal striving in line with environmental pressures or internal sanctions. Intrinsic goal striving is preferred by individuals with positive self-regard, and it can be facilitated from outside by teachers who provide autonomy support (e.g., when law school faculty provide autonomy support, grade point average improves).

In addition to goal content, *structural features of goals* also affect goal pursuit. For example, acting on one's goals is commonly believed to depend on the strength of the goal ('I really want to reach goal x!'). But most tests of this goal strength–behavior relation are only based on correlational studies that preclude causal inferences. A recent meta-analysis by Webb and Sheeran (2006) took a closer look at this assumption by only selecting studies where the strength of the goal was manipulated relative to a control group, and differences in subsequent goal-directed behavior were observed. They found 47 experimental tests of the intention (goal)–behavior relation that actually used an experimental manipulation of the strength of the goal (intention). The meta-analysis showed that a medium-to-large change in strength of intention ($d = 0.66$) led to a small-to-medium change in respective behavior ($d = 0.36$).

But meeting one's goals does not only depend on the strength of the goal; it also depends on what kind of aspiration or standard is specified in the goal (i.e., whether the person wants to achieve a lot or only a little). Locke and Latham (2006) reported that participants are more likely to attain challenging goals that are spelled out in specific terms than moderately specific goals or challenging but vague goals (i.e., 'do your best'). This effect has a number of prerequisites: frequent performance feedback, strong goal commitment, low goal complexity, and the presence of necessary skills and means to the individual. What does not seem to matter is whether the goal is determined from outside (assigned goals), freely chosen by the individual (self-set goals), or chosen in interaction with others (participative goals). As potential mediators of the goal-specificity effect, Locke and Latham pointed to heightened persistence, attention to the execution of goal-directed behaviors, a greater readiness to plan the goal pursuit, and to feedback and self-monitoring advantages.

Goal attainment is also affected by structural features such as goal orientation (i.e., approach vs avoidance orientation, promotion vs prevention, learning vs performance orientation, and low vs high identity-relation). Framing of the orientation of social goals in terms of *approach versus avoidance* clearly affects their attainment. For instance, striving for the goal of making new friends versus striving for the goal of not being lonely produces quite different outcomes. With respect to the outcome variable of interpersonal satisfaction, framing a goal in terms of avoiding loneliness leads to less favorable results than framing it as making new friends (Elliot et al., 2006). These differences seem to be mediated by differential attention and memory processes, differential interpretation and weighting of available information, and differential evaluation of the progress made toward goal attainment.

Higgins (2006) reported that approach goals benefit more from goal striving that makes use of eagerness-related approach strategies (such as pulling things toward oneself) than from vigilance-related avoidance strategies (such as pushing things away from oneself), whereas the reverse is true for avoidance goals. The assumed reason for this is *value from fit*. Higgins argued that people engage more in goal striving when the strategies used match the goal orientation (i.e., eagerness strategies/positive outcome focus; vigilance strategies/negative outcome focus) than when there is a mismatch (i.e., vigilance strategies/positive outcome focus; eagerness strategies/negative outcome focus). This heightened engagement in turn leads to a higher perceived value.

Framing goals in terms of *learning versus performance* has been found to matter as well (Dweck, 1996). Learning goals lead to better achievement than performance goals because they allow for a more effective coping with negative feedback. For people with performance goals, negative feedback signals failure and lack of ability and thus causes them to give up prematurely. People with learning goals, on the other hand, view negative feedback as setbacks and as valuable cues on how to focus on new strategies, ultimately furthering goal attainment. Recent research on the framing of achievement goals in terms of learning versus performance has also investigated its influence on interactions in social achievement situations (Poortvliet et al., 2007). People with learning goals are oriented reciprocally. They give information openly, and they process received information with a focus on those pieces of information that fit well and add value to their own chosen task strategy. On the other hand, people with performance goals are oriented exploitatively. They provide information to others reluctantly, and they process received information with a suspicious attitude that leads them to focus on detecting and disregarding

low-quality information that might hurt their own task performance.

Finally, it matters whether a person frames a given task goal in terms of its *identity-relatedness*. For instance, the task of solving a certain arithmetic problem can be approached with the goal of solving it effectively or the goal of becoming a great mathematician. The latter goal has been referred to as a self-defining goal or *identity* goal, as it specifies an identity as a desired end state. Self-completion theory (Wicklund and Gollwitzer, 1982) proposes that people who are committed to identity goals can undertake a variety of activities to claim identity-goal attainment, because many different behaviors indicate the possession of such identities. For a scientist, for example, such self-symbolizing activities might include engaging in professional duties (e.g., giving lectures); making positive self-descriptions (e.g., 'I discovered a new principle!'); exerting identity-relevant social influence (e.g., advising students); or acquiring respective skills, tools, and material symbols (e.g., programming skills, fast computers, large office). Failing to perform an identity-relevant activity or lacking an identity symbol produces a state of incompleteness; to restore completeness, people engage in self-symbolizing efforts by emphasizing the possession of alternative symbols or setting out to acquire new identity symbols (e.g., engaging in identity-relevant activities, describing oneself as having the required personality attributes, showing off relevant status symbols). Importantly, affirming one's general self-integrity or bolstering one's self-esteem are not sufficient to offset incompleteness regarding an identity goal; rather, one must acquire specific identity symbols (Gollwitzer et al., 2013).

Attaining one's goals, however, does not only depend on the content of the goals and their structural features. It also depends on the *context* in which the person strives for her goals. Research has differentiated various critical context variables that relate to the person's affective state, the array of competing action tendencies, and the power position of the goal striver. For instance, Tice et al. (2001) focused on negative *affect* and observed that feeling emotionally distraught (e.g., having been asked to imagine that one has caused a traffic accident that killed a child) makes it difficult to follow through with goals of not eating unhealthy food or delaying gratification to attain better long-term rewards.

Recently, researchers have also focused on the contextual variable of being in a position of *power* versus being powerless. For instance, Guinote (2008) reported that people in power procrastinate less in pursuing their goals, they persist longer in the face of difficulties, they show more willingness to try out different strategies to attain the goal, and they more readily seize good opportunities to make goal-directed responses. In addition, they more readily recognize whether a given situation can be used to serve their goals and then allow suitable situations to guide their behavior. All of this appears to be facilitated by a change in executive functioning. Powerful individuals are better than powerless ones at updating goal-relevant information (i.e., new information is monitored for goal relevance, and relevant information replaces old, irrelevant information in working memory). They are also better at inhibiting responses that may interfere with the present goal, and at switching between the main goal and respective subgoals.

The Self-Regulation of Goal Pursuit

But pursuing goals with the right content and structure in the proper situational context does not yet guarantee effective goal attainment. People often have to engage in self-regulatory thought to further their goal pursuits. For instance, picking a goal that appears desirable and feasible does not yet guarantee that one effectively strives for this goal. A person may adopt the goal to play the piano because she loves to make music and feels capable of doing so, yet actually attempting to realize this goal takes a further effort, and there are certain self-regulatory strategies that facilitate making this effort.

Instigating Determined Goal Pursuits

The *theory of fantasy realization* specifies three respective self-regulation strategies (Oettingen, 2012): mental contrasting, indulging, and dwelling. In mental contrasting, people first imagine the fulfillment of a wish or fantasy (e.g., giving a good presentation at a conference) and then reflect on the present reality that stands in the way of attaining the desired future (e.g., evaluation anxiety). Mental contrasting is a problem-solving strategy that allows people to recognize that they have not yet fulfilled their wish and that they need to take action in order to achieve the desired future. As a consequence, expectations of attaining the desired future become activated and determine a person's striving to attain the desired future. When perceived expectations of success are high, people will engage in strong goal striving; when expectations of success are low, people will refrain from doing so, and thus they will venture on alternative wishes and desired futures. In this way, mental contrasting helps people discriminate between feasible and unfeasible goals.

The theory of fantasy realization specifies two further routes to goal pursuit. People may engage either in indulging (envisioning only the attainment of the wished-for future) or in dwelling (reflecting only on the present negative reality). Neither of these mental strategies produces any discrepancy between future and reality, and thus the individual fails to recognize that actions (making responses) are necessary to achieve the desired future. Therefore, expectations of success do not become activated, and goal pursuit does not reflect the perceived likelihood of reaching the desired future. Individuals who indulge and dwell show a medium level of striving, even though the resource-efficient strategy to follow would be no engagement in the case of low expectations of success, and full engagement in the case of high expectations of success.

Various experiments support these claims. In one study (Oettingen et al., 2001: Study 4), first-year students enrolled in a vocational school for computer programming indicated their expectations of excelling in mathematics. Next, they named positive aspects that they associated with excelling in mathematics (e.g., feelings of pride, increasing job prospects) and negative aspects of reality, that is, potential personal obstacles (e.g., being distracted by peers or feeling lazy). In the mental-contrasting condition, participants had to elaborate in writing two aspects of the desired future and two aspects of the present reality, in alternating order beginning with the

aspect of the desired future. Participants in the indulging condition were asked to elaborate four aspects of the desired future only; in the dwelling condition they instead elaborated four aspects of the present reality only. As a dependent variable, participants indicated how energized they felt with respect to excelling in math (e.g., how active, eventful, energetic). Two weeks after the experiment, the participants' teachers reported how much effort each student had invested over the interim and provided each student with a grade for that time period. As predicted, only in the mental-contrasting condition did the students feel energized, exerted effort, and earned grades based upon their expectations of success. Those with high expectations of success felt the most energized, invested the most effort, and received the highest course grades; those with low expectations of success felt the least energized, invested the least effort, and received the lowest course grades. To the contrary, participants in both the indulging and dwelling conditions felt moderately energized, exerted moderate effort, and received average grades independent of their expectations of success.

A variety of studies pertaining to different life domains replicated this pattern of results, for example, experiments on studying abroad, acquiring a second language, getting to know an attractive stranger, finding a balance between work and family life, self-improvement, coping with stress, and fulfilling idiosyncratic interpersonal wishes of great importance. Furthermore, intensity of goal pursuit was assessed by cognitive (e.g., making plans), affective (e.g., feelings of frustration), motivational (e.g., feelings of energization), and behavioral (e.g., amount of invested effort) indicators. These indicators were measured via self-report or observations, either directly after the experiment or weeks later.

Recent research suggests that mental contrasting also promotes the choice of suitable means for effective goal striving. Oettingen et al. (2010) examined the mental-contrasting effects on seeking and giving help as means to an end. For college students, mental contrasting about attaining academic help (more than indulging and dwelling) led to expectancy-dependent seeking of help (Study 1), while for critical care nurses mental contrasting about helping patients' relatives led to expectancy-dependent giving of help (Study 2). Mental contrasting also enables people to master negative feedback. A series of three studies (A. Kappes et al., 2012) showed that when expectations of success were high, mental contrasting promoted the processing of relevant negative feedback (which in turn led to effective planning), protected participants' self-view of competence against negative feedback, and led to optimistic as well as effort-related (rather than ability-related) attributions in response to negative feedback.

The mediating processes of mental contrasting pertain to both cognitive and motivational processes (summary by Oettingen, 2012). As for cognitive processes, mental contrasting modulates the strength of the associative link between future and reality and between reality and instrumental means. When expectations of successfully reaching a desired future are high, mental contrasting strengthens the association between the desired future and the reality; when expectations are low, mental contrasting weakens future–reality associations. Importantly, the future–reality associations in turn mediate mental-contrasting effects on self-reported (e.g., feelings of responsibility) and other-rated intensity of goal pursuit (e.g., raters scored quality of performance on giving a talk and solving a creativity test). But mental contrasting not only links future and reality, it also connects present reality to relevant instrumental means (i.e., means instrumental to overcome or circumvent the present reality to attain the desired future). Again, the strength of the reality–behavior associations mediated intensity of goal pursuit (e.g., performance of taking the stairs instead of the elevator to achieve the goal of getting physically fit). Mediating processes of mental contrasting pertain also to motivational processes. Mental contrasting of a desired future with present reality leads to energization in terms of increased systolic blood pressure as well as self-report of feeling energized.

A recent experiment used continuous magneto-encephalography, a brain imaging technique measuring magnetic fields produced by electrical activity in the brain (Achtziger et al., 2009) to test whether mental contrasting qualifies as a sophisticated problem-solving technique. Mental contrasting was compared to indulging in a positive future or simply resting. As compared to resting, mental contrasting produced heightened brain activity in areas associated with working memory, episodic memory, intention maintenance, action preparation, and vivid visualization. That is, mental contrasting demands vividly imagining a desired future, anticipating hindrances to realizing this future, and making plans on how to overcome these barriers. The brain activity associated with indulging, on the other hand, did not differ from resting.

This latter finding raises doubts that solely engaging in highly positive fantasies about a desired future can strengthen a person's goal pursuits. Indeed, research on engaging in positive versus negative fantasies about the future supports this suspicion. Early on, Oettingen and Wadden (1991) observed that obese women who spontaneously indulged in positive fantasies about their weight loss were less successful in achieving a lower body mass index (after 4 months and 2 years) than obese women who spontaneously produced fantasies that were more negative. Moreover, Oettingen and Mayer (2002) observed that people who indulge in positive fantasies (valence and frequency) show comparatively weaker academic achievements (i.e., achieving a good grade in a psychology class), professional achievements (i.e., finding a job after graduation), interpersonal relations (i.e., finding a romantic partner), and health (i.e., recovering from hip surgery). More recently, H.B. Kappes and Oettingen (2011) investigated the effects of experimentally induced positive fantasies on energization, hypothesizing that low energy is a mechanism by which positive fantasies translate into poor achievement. Indeed, induced positive fantasies resulted in less energy (as measured by physiological and behavioral indicators) than fantasies that questioned the desired future, negative fantasies, or neutral fantasies. Additionally, energy measured right after the induction of the positive fantasies mediated accomplishment in everyday life a week later. Finally, positive fantasies yielded a larger decrease in energy when they pertained to a more rather than less pressing need (e.g., need achievement) further suggesting that it is the positivity of fantasies that quells energization. Altogether the results indicate that one reason positive fantasies predict poor

achievement is because they sap energy required to pursue the desired future.

Dealing with Hindrances on the Way to Goal Attainment

One very powerful self-regulation strategy of overcoming hindrances to goal attainment is planning out one's goal striving in advance. Gollwitzer (1999) proposed a distinction between goal intentions and implementation intentions. Goal intentions (goals) have the structure of 'I intend to reach Z!' whereby Z may relate to a certain outcome or behavior to which the individual feels committed. Implementation intentions (plans) have the structure of 'If situation X is encountered, then I will perform the goal-directed response Y!' Both goal and implementation intentions are set in an act of will: The former specifies the intention to meet a goal or standard; the latter refers to the intention to perform a plan. For instance, a possible implementation intention for the goal intention to eat healthy food could link a suitable situational context (e.g., one's order is taken at a restaurant) to an appropriate behavior (e.g., asking for a low-fat meal). Whereas goal intentions merely specify desired end states ('I want to achieve goal X!'), the if-component of an implementation intention specifies when and where one wants to act on this goal, and the then-component of the plan specifies how this will be done. Implementation intentions thus delegate control over the initiation of goal-directed behavior to a specified opportunity by creating a strong link between a situational cue and a goal-directed response.

Evidence that forming if–then plans enhances rates of goal attainment has been obtained in many studies on a whole array of different goals (e.g., academic, health, interpersonal). A recent meta-analysis (Gollwitzer and Sheeran, 2006) involving over 8000 participants in 94 independent studies revealed a medium-to-large effect size ($d = 0.65$; Cohen, 1992) of implementation intentions on goal attainment on top of the effects of mere goals. This size of the implementation intention effect is noteworthy, given that goals by themselves already have a facilitating effect on relevant behavior enactment (Webb and Sheeran, 2006).

Research on the underlying mechanisms of implementation intention effects (summary by Gollwitzer and Oettingen, 2011) found that implementation intentions facilitate goal attainment on the basis of psychological mechanisms that relate to the anticipated situation (specified in the if-part of the plan), the intended behavior (specified in the then-part of the plan), and the mental link forged between the if-part and the then-part of the plan. Because forming an implementation intention implies the selection of a critical future situation, the mental representation of this situation becomes highly activated and hence more accessible. This heightened accessibility of the if-part of the plan has been observed in several studies testing this hypothesis by using different experimental paradigms: for example, lexical decision tasks, the dichotic-listening paradigm, and cued recall. Moreover, forming implementation intentions not only heightens the activation (and thus the accessibility) of the mental presentation of the situational cues specified in the if-component, it also forges a strong associative link between the mental representation of the specified opportunity and the mental representation of the specified response. These associative links are quite stable over time. Moreover, mediation analyses suggest that cue accessibility and the strength of the cue–response link together mediate the impact of implementation intention formation on goal attainment.

Gollwitzer (1999) suggested that the upshot of the strong associative (critical situation – goal-directed response) links created by forming implementation intentions is that – once the critical cue is encountered – the initiation of the goal-directed response specified in the then-component of the implementation intention exhibits features of automaticity, including immediacy, efficiency, uncontrollability, and redundancy of conscious intent. Consistent with this idea, there is plenty of evidence now that if–then planners do act quickly, deal effectively with cognitive demands (i.e., speed-up effects are still evident under high cognitive load), show uncontrolled attention to the specified cues, and do not need to consciously intend to act in the critical moment (i.e., implementation intention effects are observed even when the critical cue is presented subliminally).

The postulated and observed component processes underlying implementation intention effects (enhanced cue accessibility, strong cue–response links, automation of responding) mean that if–then planning allows people to see and seize good opportunities to move toward their goals. Fashioning an if–then plan thus strategically automates goal striving; people intentionally make if–then plans that delegate control of goal-directed behavior to preselected situational cues with the explicit purpose of reaching their goals. This delegation hypothesis was tested in a functional magnetic resonance imaging study reported by Gilbert et al. (2009). In this study, participants had to perform a prospective memory task on the basis of either goal or implementation intention instructions. Acting on the basis of goal intentions was associated with brain activity in the lateral rostral prefrontal cortex, whereas acting on the basis of implementation intentions was associated with brain activity in the medial rostral prefrontal cortex. Brain activity in the latter area is known to be associated with bottom-up (stimulus) control of action, whereas brain activity in the former area is known to be related to top-down (goal) control of action. Support for the delegation hypothesis also comes from studies using critical samples (see Gollwitzer and Oettingen, 2011) – that is, individuals with poor self-regulatory abilities such as people with schizophrenia, people with substance abuse disorders, people with frontal lobe damage, and children with attention-deficit/hyperactivity disorder (ADHD).

Research on the facilitating effects of forming implementation intentions on goal attainment has targeted all of the four major problems that are known to doom effective goal striving: getting started, staying on track, failing to call a halt to futile goal striving, and overextending oneself. Given that forming implementation intentions automates goal striving, people who form implementation intentions should actually have it easier when they are confronted with these four central problems of goal implementation. Indeed, numerous studies suggest that problems of getting started on one's goals can be solved effectively by forming implementation intentions. But many goals cannot be accomplished by a simple discrete one-shot action as they require that people keep striving over an

extended period of time. Such staying on track may become very difficult when certain internal stimuli (e.g., being anxious, tired, overburdened) or external stimuli (e.g., temptations, distractions) interfere with ongoing goal pursuit. Implementation intentions have been found to prevent the negative influence of interferences from inside (e.g., mood) and outside the person (e.g., disruptions by attractive video shows). The self-regulatory problem of calling a halt to a futile goal striving (i.e., disengaging from a chosen but noninstrumental means or from a chosen goal that has become unfeasible or undesirable) can also be ameliorated by forming implementation intentions. And finally, when task performance is regulated by implementation intentions, using different ego-depletion paradigms, research participants who used implementation intentions to self-regulate in one task do not show reduced self-regulatory capacity in a subsequent task.

A new line of research on implementation intentions has been stimulated by Aristotle's concept of akrasia (lack of willpower). It is argued that any willful strategy of goal striving (such as if–then planning) has to prove itself under conditions where people commonly fail to demonstrate willpower. Three such conditions have been analyzed so far: (1) situations in which a person's knowledge and skills constrain performance such as taking academic tests, (2) situations in which an opponent's behavior limits one's performance such as negotiation settings, and (3) situations in which the wanted behavior (e.g., not snacking, not littering) runs into conflict with the respective impulsive antagonistic responses. For all of these situations, forming implementation intentions qualifies as an effective self-regulation strategy (see Gollwitzer and Oettingen, 2011).

The litmus test for any strategy to improve willpower is enhanced performance in a *delay of gratification* task. Children with deficits in inhibitory control (i.e., children with ADHD) are known to have particularly pronounced problems with delaying gratifications. Accordingly, Gawrilow et al. (2011) investigated whether delay of gratification can be facilitated by forming implementation intentions even in children with ADHD. Only when the goal intention to delay gratification was furnished with an implementation intention a heightened ability to delay gratification was observed.

Current Goal Research: Interventions

Knowledge about effective self-regulation strategies of goal pursuit allows one to construct interventions that teach people how to effectively pursue their goals. One such intervention (see Oettingen, 2012) combines mental contrasting with forming implementation intentions into a metacognitive strategy called mental contrasting with implementation intentions (MCII). In a recent intervention study with middle-aged women (Stadler et al., 2009), participants were taught the cognitive principles and individual steps of the MCII self-regulation strategy. This intervention allowed participants to apply MCII to their idiosyncratic everyday wishes and concerns on improving their lifestyle. Specifically, participants were taught to apply MCII by themselves to the wish of exercising more whenever possible. Participants were free to choose whatever form of exercising they wished to apply MCII to, and they were encouraged to anticipate exactly those obstacles that were personally most relevant and to link them to exactly those goal-directed responses that personally appeared to be most instrumental. As dependent measures, participants maintained daily behavioral diaries to keep track of the amount of time they exercised everyday. Overall, teaching the MCII technique enhanced exercise more than the information-only control intervention; this effect showed up immediately after the intervention and it stayed stable throughout the entire period of the study (16 weeks after the intervention). More specifically, participants in the MCII group exercised nearly twice as much: an average of 1 h more per week than participants in the information-only control group.

The MCII intervention was also used to promote healthy eating in middle-aged women (i.e., eating more fruits and vegetables), and it produced the desired behavior change effects; these persisted even over the extensive time period of 2 years (Stadler et al., 2010). In another study, Adriaanse et al. (2010) targeted the negative eating habit of unhealthy snacking in college students. MCII worked for both students with weak and strong such habits and, notably, it was more effective than mental contrasting or formulating implementation intentions alone. Moreover, MCII was observed to benefit chronic back pain patients in increasing their health behaviors (Christiansen et al., 2010). Over a period of both 3 weeks and 3 months patients increased their physical mobility as compared to a standard treatment control group. Physical mobility was measured by objective (i.e., bicycle ergometer test and number of lifts achieved in 2 min) and subjective indicators (reported physical functioning). Finally, MCII has shown beneficial effects outside the health area. For example, it benefited study efforts in adolescents preparing for standardized tests (Duckworth et al., 2011). Together, these findings suggest that MCII is a cost- and time-effective self-regulation technique when it comes to the effective self-regulation of goal pursuit.

Summary

Research on goals has started to conceptualize the individual as the master of her own fate. People only need to apply empirically tested self-regulation strategies (e.g., mental contrasting and forming implementation intentions) to effectively attain their goals. These strategies allow realizing idiosyncratic wishes according to what is desirable and feasible. When applied in metacognitive form, these strategies can liberate people from being bound to erroneous engagement and from being plagued by action control deficits (e.g., impulsivity).

Motivation and Emotion: Reflections on the History of an Attributional Approach

Bernard Weiner, University of California, Los Angeles, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article outlines the history of an attributional approach motivation and emotion from the author's perspective. The article highlights the underlying empirical and theoretical consistency in the apparent face of changes in directions. In addition, the article discusses the legacies that have remained.

In this article, I consider the history of my attribution work, conducted with many outstanding students and colleagues, and focus on the underlying constancy in the apparent face of changes in directions. In addition, I stress the legacies, if any, that were left behind. I found Freudian insights valuable because I realized I had to navigate between three forces: the id-derivative hedonic biasing pushing me to overestimate success, increasing my pride and self-esteem; the superego forces directing me to recognition of failure; and finally, to the realistic position fostered by the ego that some of our work has merit and hopefully will have staying power, whereas other ideas have already been relegated to the dustbin of history. This article is heavily driven by the id forces and attempts to show the underlying empirical and theoretical unity of this work. I begin with some broad theoretical observations and then turn to specific research.

First, another number three in addition to the Freudian taxonomy is pertinent to this overview. I am the product of (at least) three traditions I inherited from my mentor, John Atkinson: one I maintained and the other two I rejected. The tradition I held, or at least came to embrace, is trying to create a so-called 'grand' theory of motivation in the shadows of Hull and Lewin. That is, I eventually wanted to develop a conceptual system, a system of interrelated constructs, which would transcend specific phenomena and identify the 'deep structures' of motivated behavior. Hence, the work of my colleagues and me has addressed not only achievement strivings but also helping, aggression, reactions to the stigmatized, impression formation, punishment, emotions, blame and responsibility, political ideology, coping, change programs, consumer reactions, poverty, and more. I have had less interest in specific observations and data than in the general theory guiding the research. I once gave a talk on an attribution analysis of poverty and was asked by an approving, altruistic-type student how I happened to develop this interest. I think some serious commitment to social justice was the expected response. To her great dismay and disappointment, I replied that I was not particularly interested in poverty and could just as happily written about wealth if it was subject to an equally interesting attribution analysis. This is a lost tradition in motivation: in my day, it was Hull versus Tolman, or Spence versus Atkinson. Theories, not specific research studies, defined the field. I am sorry or disappointed to believe that this contribution of our work has not met with great success.

One of the two traditions I left behind is another specific grand theory – Expectancy/Value theory. I do not doubt that both expectancy and value play important roles in choice and behavior, as has been well documented. Indeed, this may be more consistent with common sense than is attribution theory – what we do depends on what we expect to get and the likelihood of getting it. But it does not, or has not, readily incorporated emotions and the moral aspects of behavior to which I have been drawn.

The second tradition I gave up is a combination of individual differences and projective measurement. I scored thousands of Thematic Apperception Tests (TATs) as a student and a beginning assistant professor, and I left graduate school without any publications. But there was a lot of data in our file drawers. I blame both the measurement instrument and the individual difference approach for the publication failures. Searching for interactions, particularly with individual differences that are considered traits or motives (as opposed to, for example, ideologies or temperaments) generally fails to yield replicable data or capture a great deal of behavioral variance. My preference has been not only to find main effects but main effects that are beyond doubt or question so that replication in front of a classroom is a certainty. I am disturbed by the movement to find or create phenomena that contradict common sense, which so often can't replicate, as now is being discussed regarding the alleged priming effects on behavior. I think in the near future popular phenomena including stereotype threat, ego depletion, value affirmation, implicit self-esteem, implicit attitudes, and a number of others that defy common sense and highlight the unconscious will suffer the same negative fate. We are in an era where the unconscious and the unbelievable have ascended; I am reminded of my work with the TAT.

But if something does not defy common sense, then it often is common sense and findings are not given much credit, labeled as 'bubba psychology,' as though such effects need not be incorporated by theories. I think my goal, or at least one goal, has been to create a conceptual framework that systematizes common sense or the way that the naive person thinks. I inherited this from Fritz Heider. I also believe that the vast majority of our findings are true yet the data are not trivial, particularly when placed within a larger theoretical framework. I must admit that some of these caveats or guiding principles preceded and directed my research, whereas others followed from the research findings. With this background or foundation in mind, let me now turn to some historical developments.

The 1960s Decade: Finding Predictors of Achievement

As already indicated, the bulk of my research as a graduate student with Atkinson was consigned to a no-significant-effects file drawer. Upon leaving graduate school, my focus remained on achievement motivation, although I supplemented that with research on motivation and memory to increase my publication rate. The main issue regarding achievement motivation that I addressed was what psychological variables might predict achievement striving, since I did not think achievement motives as assessed with the TAT did that. My search brought me to Julian Rotter, who in 1966 published his monograph on locus of control. This intuitively seemed a good road to follow: locus of control was a cognitive variable at a time the field was talking about but not specifying the cognitive determinants of behavior; it was assessed with an objective rather than a projective individual difference measure; and his data regarding expectancy change in skill versus luck situations were quite replicable and systematic.

Therefore, I conducted a study in around 1967 with an undergraduate, Penelope Potepan, where we gave the TAT, which was scored for achievement needs, and the Locus of Control Scale and then examined their relations. Some obvious conclusions, primarily about locus of control, dawned on me during this research. First, it was evident that locus of control for success had to be separated from locus of control for failure. One reason for this is that if success is ascribed to high ability, then failure by that individual is not ascribed to low ability. That is, one does not say I succeeded because I am smart but failed because I am dumb. But this was not the case for effort: for the same person, high effort might be construed as a cause of success and low effort a cause of failure. And this resulted in the next obvious fact: ability had to be separated from effort when considering causal locus, although both are internal determinants of achievement. I believe that a good part of my scientific work has been determining the ways in which effort and ability differ, ultimately resulting in a sin versus sickness designation given their absence, seemingly far from where I started but in reality quite close.

Around 1968, so toward the end of the 1960s, a number of events took place of personal research significance. First, I read a book by Richard deCharms, a student of McClelland, in which he mentioned a study of moral evaluation where a person did not repay a debt either because he did not have the money or spent it on something else. I connected this with ability and effort and devised an experiment with Andy Kukla in which we varied effort, ability, and outcome and examined evaluations by others. For example, a person of high ability and low effort failed an exam; evaluate this person. I thought I was doing research on achievement motivation but this had nothing (or little) to do with that topic inasmuch as this is a study of moral evaluation. This research was published in 1970 and became designated a 'citation classic' when it had 100 citations. Today, with Google Scholar, one can get 100 citations just counting letters from your mother.

This publication had a peculiar history. I submitted a three-study manuscript to what is now JPSP, where Bill McGuire, the verbose, critical, and smart, was the editor. He sent me something like a ten-page single-spaced critique, asking for revision. By the time I returned it, the manuscript contained four studies, and he again asked for revision with about a five-page review. Another round yielded an additional experiment and a shorter review. Finally, a six-study manuscript was accepted. It helped my visibility greatly and remains my second most cited empirical paper (exceeded only by the study of stigma I published about 20 years later with Ray Perry). It also taught me the value of replication and multiple-study publications.

Linked with this advance was a six-person conference organized by Hal Kelley that also included Ned or Edward Jones and Dick Nisbett. There I realized I was working within a framework called attribution theory, although I had never seriously (if at all) read Heider or Kelley or Jones. Attribution theorists were social psychologists influenced by quite a different literature than the history that was guiding me, which included Hull, Lewin, Atkinson, and Rotter as well as phenomena related to learning schedules, resistance to extinction, expectancy of success, and the effects of success and failure on achievement performance. I was trained in personality and motivation and not in social psychology.

Another important determinant of my subsequent research life emerged from the Jones-Kelley attribution conference: a paper written with Irene Frieze, Andy Kukla, Henry Reid, Stan Rest, and Bob Rosenbaum. This manuscript contained the beginning of our theoretical analysis of the ability versus effort distinction. There it was stated the reason that luck versus skill tasks have different effects on expectancy, which Rotter had documented and is certainly true, is not because of their locus differentiation but because the perceived causes of the outcomes at these tasks varied on endurance or stability. Luck comes and goes; skill endures. Hence, luck and skill differ in something other than locus. That is, I was expanding the properties of causal beliefs and specified causal stability as the predictor of changes in expectancy of success. I also argued that locus influenced affect (pride) or value, hence trying to remain within the Expectancy/Value framework of Atkinson but placing the data within an attributional framework. More specifically, it was suggested that the relation between expectancy of success and pride presumed by Atkinson is mediated by locus attributions – success at a low expectancy or difficult task gives rise to person attributions and thus high pride, whereas success at a high expectancy of success or easy task promotes situation attributions and hence low pride. These were core theoretical advances for our approach.

The book that emerged from the conference, published in 1972, had a significant impact on the field of social psychology and helped to usher in a nearly two decade era during which attribution theory was at the center of research activity. It temporarily replaced the anti-commonsense dissonance approach. As I already stated, we now have returned once again to the non-commonsense approach (aided by neuromania).

The 1970s: Refinement, Reflection, and Replication

The greater part of the 1970s involved theoretical refinement and some elaboration. First and foremost was that a graduate student, Bob Rosenbaum, introduced the idea of control as a third property of causes. I was initially unresponsive to this because I felt theoretically overwhelmed already and was not

sure how it would be disentangled from locus and stability, which accounted for affect and expectancy. But he proved more than correct. I then began to understand that causes could be placed within a three-dimensional space, with some difficulties, and that they varied quantitatively, not qualitatively. This provided a theoretical foundation that framed two major questions for that period: what are the antecedents of achievement-related causal beliefs and what are their consequences.

Rather than pursuing individual difference antecedents, for example, high need for achievement might give rise to effort beliefs and high locus of control to internal beliefs regarding the determinants of performance, I looked now to social psychology and particularly to Hal Kelley. With Irene Frieze, we explored the informational antecedents of effort and ability beliefs such as consistency and distinctiveness; and with Anna Kun, we considered some of the schemata antecedents, examining the distinction between necessary versus sufficient causality. At that time, it was also firmly established with a number of students that indeed stability rather than locus influences expectancy of success. As well, the ability/effort distinction on evaluation was replicated a number of times: there is no doubt that most reward is allocated to the low-capacity person who overcomes this handicap through hard work and most punishment is given to the high-capacity individual who fails because of not trying. These represent our moral heroes and moral villains. I have to admit some disappointment when critics address the replication issue in social psychology and do not recognize this body of knowledge.

This all became synthesized for a second time (the first was the chapter in the 1972 attribution theory book spearheaded by Jones and Kelley) in a manuscript published in the *Journal of Educational Psychology* in 1979 entitled "A Theory of Motivation for some Classroom Experiences". This article was invited by the editor, Sam Ball; I otherwise would not have undertaken it. On my Google Scholar listing, this is my second most cited journal article.

Then, as the 1970s came to a close, some new research directions emerged that pulled me away from achievement motivation and dominated the remaining years of my career. These shifts were toward emotions and interpersonal motivation, with the latter umbrella including, as earlier listed, help giving; impression management, especially excuses and confession; reactions to the stigmatized; aggression; blame and responsibility; political ideology; poverty; and punishment.

I was glad to leave or at least supplement the achievement research because achievement performance, and especially grade point average, is an overdetermined and complex index, making it difficult to predict and for attributions to carry much predictive variance. I am much more comfortable predicting judgments of others, as in the research with Kukla on evaluation, with Frieze on causal information, and with Kun on causal schemata.

The Late 1970s and Most of the 1980s

I am not exactly sure when the shifts to emotion and interpersonal behavior took place or even if there was a specific time or event. I had long looked on Atkinson's motivation formula with suspicion, not because it was an Expectancy/Value theory but because I did not know of evidence that the primary affect associated with achievement success is pride or that the main failure-produced affect is shame, which he had presumed. Along with Dan Russell and David Lehrman, we conducted some simple studies to examine this question. For example, in an early investigation we merely asked participants to recall a time they succeeded or failed and to recount the emotions that were experienced.

It is not surprising that many emotions were reported. The clear companion to success is happiness and the corresponding affect accompanying failure is unhappiness. This is closer to the Freud/Hull pleasure/pain distinction rather than to pride and shame, as Atkinson had specified. But pride was also reported for success, along with emotions including gratitude, relief, surprise, and many others. The failure-related affects comprised a longer list, including shame but also anger, guilt, hopelessness, helplessness, humiliation, regret, and more. Similar self-report experiments that involved feelings when others succeeded and failed generated additional emotions including admiration, envy, sympathy, pity, and more.

Previously, I regarded causes and causal dimensions as the foundation of our attribution theory and asked what are their antecedents and consequences. But now I shifted focus and asked what are the antecedents of emotions and what are the motivational consequences of feeling states. I limited the antecedents to causal beliefs and/or causal dimensions and began to create a cognitive or attribution taxonomy of emotions, asking what causal dimension placements give rise to what feelings.

I also then realized I was beginning to develop a theory of motivation in which events give rise to causal interpretations that arouse emotions, which goad action. This was a thinking–feeling–acting sequence, hence incorporating the traditional tripartite division of psychology into cognition, emotion, and conation. This temporal sequence captured what I believed to be the 'deep structure' of motivation. It also was becoming clearer to me that this could serve in the 'grand theory' mold of a cognitive theory of motivation, but the key cognition was causal belief and not expectancy of success.

With Sandra Graham, I explored the dimensional antecedents of pity (uncontrollable causality), anger (external, controllable causality), and guilt (internal, controllable causality). I now think there are about 15 or 20 such cause–affect associations that may be described as necessary or sufficient relationships. These include, for example, stable causality for failure with helplessness or hopelessness, unstable causality for failure and hope; controllable causality for other success and admiration; external controllable causality for personal success with gratitude; and, of course, internal causality for success and pride.

We also showed that conveying these emotions provide cues for personal beliefs about causes; that is, there are relations going from causal dimensions to emotions as well as from communicated emotions to causal beliefs. For example, conveying pity tells someone that their failure was uncontrollable, while communicating anger reveals beliefs of controllable causality. This brought more social psychology into the study of emotions. While doing this I also pursued the moral components of achievement strivings with Jonathon Brown,

documenting the positive moral value of succeeding because of high effort.

But my main desire, a full test of the proposed cognition–emotion–action theory of motivation, awaited the detour from achievement performance to a domain where judgments regarding behavior were possible as the dependent variable. I found that in the area of helping behavior.

A series of research investigations was then conducted in the helping domain, primarily with Greg Schmidt and Hector Bentancourt. The paradigm was simple – alter perceptions of perceived control of a need for help, measure affects of anger and sympathy, and get some dependent variable that reflects help. For the latter we often used lending class notes (in those days, just sending the notes over the computer and therefore not losing hold of them was not yet prominent). The pattern of findings was very clear and replicable – control over a need (specifically, going to the beach instead of to class) gives rise to annoyance and neglect by others, whereas lack of control (needing the notes because of eye problems) arouses sympathy and help giving. Conceptually, this was similar to failing a test because of not studying and subsequent punishment versus failing because of lack of capacity and subsequent withholding of punishment, as I had shown with Kukla. But in that research affects were not included and now, about a dozen years later, they were considered as bridging the gap between thinking and doing. I first published the helping data in 1980, in what is my third most cited empirical article.

It was then a small step to recognize that one does not want to be perceived as in control of a need and to not have acted to resolve this problem. It is known that this gives rise to anger in others and neglect: part of our commonsense wisdom in everyday interactions. I then began another series of studies, with Jim Amirkahn, Valerie Folks, Gregg Gold, Sandra Graham, Orli Peter, Seiji Takako, and others on the topic of impression management, managing perceptions of others by using excuses or offering an apology or confession. The positive effects of changing impressions from controllable to uncontrollable, or what is labeled an excuse, or altering person perception by showing remorse and a full confession, are quite powerful and unquestionable. Valerie Folks extended this to reactions of consumers to companies; this field of study now often calls upon attribution theory.

Given these newer advances, I felt it was time for a more comprehensive theoretical statement and wrote a manuscript for *Psychological Review*, published in 1985 and titled "An Attributional Theory of Achievement Motivation and Emotion". This article then became expanded into a monographic book, without achievement in the title. The *Psychology Review* article and subsequent book appeared when I was about 50 years old; they are by far my most cited contributions. This is common in psychology, so for those of you not yet 55 and not sufficiently cited, do not fret!

The Very Late 1980s, the Era of the 1990s

It was evident that I had now shifted attention away from expectancy and the stability dimension, and away from pride and the locus dimension, the core themes of an attributional analysis of achievement strivings, and moved toward other-perceptions of control, their consequences, and how to alter them as exemplified in studies of help giving and impression management. I am again not sure what produced the next less major shift, but I turned from the controllability of a specific action such as needing class notes to the controllability of a condition. The conditions were stigmas, and they included AIDS, homosexuality, obesity, schizophrenia, and others. At that time, in the late 1980s, Ray Perry, Judy Chipperfield, and I initiated research on perception of the causes of stigmas. Once again these were simple judgment studies where instead of varying ability and effort, we described heart disease as due to genetics or an unhealthy lifestyle, or AIDS as due to promiscuous sexual behavior or a blood transfusion, and so on. The results were quite clear – perceived controllability for a stigma has very negative attitudinal and behavioral consequences, whereas uncontrollability is linked with positive other-perception in terms of moral evaluation. In the early 1990s, I wrote a paper for the *American Psychologist* with sin and sickness in the title, and I realized this also could describe the absence of effort (sin) versus the absence of ability (sickness). This fully integrated my achievement research with the studies of interpersonal behavior. Stigma researchers now often turn to these ideas so that this work has had some impact on health psychology, which now recognizes personal responsibility or controllability as the central differentiating property of stigmas.

This line of research also resulted in a more serious consideration of morality and the importance of perceptions of responsibility. I realized I had to move from causal control to personal responsibility because not all controllable transgressions are punished. There are mitigators such as a very young age or mental illness that sever the relation between control and anger and punishment. In 1995, I published a book on personal responsibility and in 2006 followed this with a book focusing on social justice and social emotions that expanded these ideas and considered the concept of responsibility in greater detail.

Into this Century

Again, a few related lines of research were opened by the prior topics that extended into the year 2000 and beyond. Foremost among them was the notion that justice is judged differently by liberals and conservatives. We all know that liberals tend to perceive environmental causality for social ills such as poverty (e.g., lack of educational opportunities), whereas conservatives perceive personal responsibility for poverty (e.g., laziness, lack of saving). In early research with Gail Sahar and later with Lisa Farwell and Danny Osborne, we returned to individual differences, but not involving needs or motives but rather regarding more embracing political ideologies, relating them to perceptions of control and beliefs about welfare (another index of helping). In addition, with Christine Reyna and P.J. Henry, we explored how attributions relate to punishment, differentiating retributive punishment meted out for controllable actions as opposed to utilitarian punishment. Finally, with Udo Rudolph and Scott Roesch, we completed a meta-analysis of nearly 40 research studies that verified the attribution–affect–action conception in both the helping and aggression domains. I have read an aphorism recently that poetically stated: my head said

something was interesting and unusual; my heart said to try it. That almost captures the theory.

Summing up

Hal Kelley once asked me: "So, what are you mucking around with nowadays?" as though I shifted around from one topic to another. But I regard my career as more unified than that, following a rather narrow or circumscribed attribution path that logically progressed from one step to another. I think at each step a brick was laid for a scientific structure, sometimes an empirical and/or sometimes a theoretical residue. I think each individual empirical finding is in accord with common sense. I hope so. I also think that the whole is different from, or other than, the sum of the parts and at the genotypic level transcends common wisdom. The empirical observations should be judged as true or false; the theory should be judged as useful or not.

The common empirical theme throughout much of my work surprisingly (to me) concerns moral evaluation. As I mentioned earlier, my most cited empirical study was with Ray Perry on stigma evaluation and perceptions of control, published in 1988. The second most cited empirical work was published in 1970 with Andy Kukla and relates to achievement evaluation when the causes of success and failure are ability and effort. And my third most cited empirical work was published in 1980 and examines help-giving when classroom-related aid is desired because of controllable or uncontrollable causes. It is clear that these all explore the phenomenon of moral evaluation. The data are without doubt regarding the effects of controllability (bad, immoral) and uncontrollability (good, moral) on the emotions and judgments of others as related to stigmas, achievement evaluation, and desires to help others.

The underlying and unifying theoretical system is that events and states, whether succeeding or failing an exam, having a stigma, or needing help, give rise to specific causal interpretations that are categorized into causal properties. These causal categories, in turn, arouse emotions, that then guide actions. This thinking–feeling–acting system is more easily tested in interpersonal contexts, but applies as well in intrapersonal settings and in achievement contexts. Hence, the underlying theory has generality across motivational domains and to both the self and others.

The data so briefly described above will have to be accounted for by any psychological theory, so even if this attribution conception does not stand the test of time, I believe that the data will endure. On the other hand, I also regard the theoretical representation as having strength.

Motivation in Australian Aboriginal Populations

Rhonda G Craven and Alexander Seeshing Yeung, Institute for Positive Psychology and Education, Australian Catholic University, Strathfield, NSW, Australia

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Many Indigenous people worldwide are more disadvantaged compared with their non-Indigenous peers. Australian Indigenous people have been identified as one of the most disadvantaged groups in the world. Consistent with positive psychology approaches, motivational constructs have been identified for non-Indigenous students from diverse cultural backgrounds as critical psychological drivers that facilitate desirable educational outcomes and life opportunities beyond schooling. However, due to limited empirical research with Indigenous populations, less is known about the role of motivational constructs for this population. This article explores the importance of motivational constructs for Indigenous populations with a focus on Indigenous Australian students.

Introduction

Many Indigenous people worldwide are more disadvantaged compared with their non-Indigenous peers as measured by diverse socioeconomic indicators. For example, in Australia and the USA, low numbers of Aboriginal and Native American students complete postsecondary education (Australian Bureau of Statistics (ABS), 2008; US Department of Education, National Center for Educational Statistics, 2008). Given that education predicates life's opportunities, it is of dire concern that generations of Indigenous people from different countries do not achieve commensurate educational outcomes compared with their non-Indigenous peers. The latter contributes to a lack of self-reliance, persistent intergenerational socioeconomic disadvantage, ensuing loss of talent, and undermining nations' prosperity and well-being.

In Australia, national reports and all Australian governments in the last three decades have identified that Indigenous Australians are the most significantly disadvantaged Australians on all socioeconomic indicators including education, and have the highest school dropout rate of any cultural group in Australia (e.g., ABS, 2008; Commonwealth of Australia, 2011). Recent research has also acknowledged that Indigenous Australians are one of the most disadvantaged populations in the world (see Yeung et al., 2013). Many Indigenous Australian students leave school before completing Year 10 of high school, fail to complete the final 2 years of high school (Years 11 and 12), and of those who complete the final years of schooling, fail to gain entry to university. This situation led the Ministerial Council on Education, Employment, Training, and Youth Affairs (MCEETYA, 2006) to conclude that: "These outcomes limit the postschool options and life choices of Indigenous students, perpetuating intergenerational cycles of social and economic disadvantage" (p. 4). Additionally those Indigenous Australians that qualify for university entry have lower completion rates than their non-Indigenous peers. Shergold (2013), who had responsibility for the oversight of Indigenous programs in Australia for over 20 years, has emphasized that, while the governments he served strived to make a positive difference, little progress had been made.

Part of the systemic failure to address Indigenous disadvantage in Australia and elsewhere in the world (e.g., US Department of Education, National Center for Educational Statistics, 2008) can be attributed to research with Indigenous populations employing deficit modeling approaches. Deficit models focus on the failure of Indigenous people, their communities, and social systems to address disadvantage (Riley and Ungerleider, 2012). Deficit approaches result in lower expectations becoming entrenched in individual mindsets, communities, organizations, and policy. For example, Zubrick et al. (2006: vi) have noted that in Australia:

> There has been tacit acceptance of the non-achievement of educational standards by Aboriginal children and young people. The resultant acceptance of this lack of educational success has a cumulative effect. It is based on the belief that Aboriginal children and young people will never reach their full potential and if they fall behind society then welfare will protect them. Their low level of educational success is accepted as a normative expectation.

In contrast, some researchers have attempted to address the issues from a more positive perspective. This perspective has gained increasing attention within educational psychology research with Indigenous populations with a focus on explicating what seeds success. This new direction capitalizes upon a positive psychology approach (or asset-orientated approach) to optimize the psychological resources and well-being of Indigenous students (Craven and Bodkin-Andrews, 2006; McInerney, 2008; McInerney and King, 2013). Positive psychology approaches focus on identifying and emulating how well adjusted and healthy individuals get the most out of life. Fundamental to this new direction in research with Indigenous populations is examining the role of motivational constructs in facilitating desirable educational outcomes and positive pathways beyond schooling that enable Indigenous people to both succeed and flourish. As such, researchers have gone beyond the previous emphasis on the socioeconomic disadvantages these students experience to identify psychological factors that drive academic success. Researchers have started to investigate the psychological well-being of Indigenous students (e.g., Purdie and McCrindle, 2004), their motivation in schoolwork (e.g., McInerney, 2003, 2008), and their self-concept (e.g., Craven and Bodkin-Andrews, 2006). Their new findings have broadened our knowledge about the

disadvantage Indigenous students suffer and have enabled us to identify potentially potent psychosocial tools to inform intervention.

The purpose of this article is to discuss some of these new directions in relation to Indigenous Australians and delineate significant motivational theory and research that have the potential to facilitate Indigenous academic success and well-being. First, we provide an overview of the pervasiveness of Indigenous Australian educational disadvantage. Next, we discuss recent advances in positive psychology approaches and motivational theory. We then provide an overview of some examples of recent research that has capitalized upon positive psychology approaches, motivation and self-concept theory and research to advance our understandings of the importance of adaptive motivational orientations for Indigenous Australian students. Finally, we emphasize the potential of key research-derived motivational constructs for facilitating Indigenous peoples to flourish.

Nature of Indigenous Australian Educational Disadvantage

Recent reports of the Organization for Economic Development and Cooperation (OECD) indicate that students who disengage from school are less likely to find employment or to remain employed during times of economic hardship (OECD, 2011). In comparison to non-Indigenous students, Indigenous Australian students in all age groups from all Australian States and Territories display lower school attendance, retention, and achievement (Craven and Bodkin-Andrews, 2006). For example, the number of Indigenous Australian students progressing into the final year of secondary schooling (Year 12) is much lower (42.9%) than non-Indigenous students (75.6%). Hence it is apparent that Indigenous students generally do less well academically than their non-Indigenous peers. These educational inequities are so pervasive that they extend across preschool through high school (De Bortoli and Thomson, 2010). This is well illustrated by results across three waves of the Program for International Student Assessment (PISA) data (2000, 2003, 2006), whereby 15-year-old Indigenous Australian students' results were well below the OECD average for reading literacy, mathematics, and science (De Bortoli and Thomson, 2010). Furthermore, reflecting the persistent nature of educational disadvantage for Indigenous Australians, over this 6-year period, there was no improvement in Indigenous students' performance.

This educational disadvantage is further exacerbated in relation to tertiary education. While in 2006 Indigenous Australians made up 2.5% (i.e., 517 200 citizens) of the total population of Australia (i.e., 21 017 200 citizens) (ABS, 2008), they were underrepresented in universities (Demosthenous, 2012). Even though university participation, commencement, and completion rates for Indigenous Australians have increased over the past two decades, these rates are not commensurate with the increase in the Indigenous population and the increased participation by non-Indigenous students in tertiary education. For example, in 2009, the gap between the retention of Indigenous and non-Indigenous students was 31.9%. Furthermore, 26% of Indigenous people, in comparison to 53% of non-Indigenous people, had a nonschool qualification in 2006; Indigenous people were also four times less likely to have a Bachelor's degree (5% as compared with 21%) and twice less likely to have an Advanced Diploma or Diploma (9% compared with 4%) (ABS, 2008).

In 2011, an Australian Government's report (Commonwealth of Australia, 2011) noted that the proportion of Indigenous 20- to 24-year-olds who had completed Year 12 of schooling or equivalent was increasing. However, even though Indigenous students who received a Year 12 certificate increased from 20% in 2001 to 26% in 2008, the proportion was far below the non-Indigenous rate of around 56%. Furthermore, demonstrating the international prevalence of this issue, education statistics for Native American students in the United States are similar to those for Indigenous Australian students (US Department of Education, National Center for Education Statistics, 2008). Given these persistent educational inequalities for Indigenous students in different countries, there is a need to identify factors that seed success to ensure that Indigenous students attain commensurate outcomes to their non-Indigenous peers and therefore enjoy similar life opportunities. Improving educational outcomes for Indigenous people also comes with significant socioeconomic benefits. For example, in Australia "if the educational level of the Indigenous population was increased to that of the non-Indigenous population, the value of this hypothetical change [to the nation] is $1.09 billion per annum" (Taylor et al., 2012: viii). Economy-wide advantages are also likely to result from improvements in the quality of life of Indigenous Australians, including more than $10 billion in extra gross domestic product by 2029, an increase in government revenue by $4.6 billion, and a reduction in government expenditure by $3.7 billion (Access Economics, 2008: iv). Hence addressing Indigenous educational disadvantage is a significant international socioeconomic issue of our time.

How to seed success in educational attainment remains unclear, particularly for Indigenous people. Indigenous education is also plagued by a paucity of evidence-based research. For example, Mellor and Corrigan (2004), in reviewing contemporary Indigenous education research, lamented the lack of empirical research noting that: "There is not, in Australia, a research tradition of quantitative measurement in the Indigenous education literature. To ignore such measurement only continues to do injustice to the gravity of the problem" (pp. 46–47). They also noted that research methodology has been limited by factors such as small case studies; focusing on a small subset of the population (e.g., communities with a high Indigenous population); isolating Indigenous education research from the broader discourses in other disciplines such as psychology, sociology, and health; and that the relation between cause and effect has been asserted rather than demonstrated by research. Clearly, there is a dearth of research being undertaken in Indigenous education yet even though such research could be used to improve the educational outcomes for Indigenous populations (Bin-Sallik, 2005). However, as yet advances in motivational theory and research have only just begun to be explored with Indigenous populations. Two such advances involve capitalizing upon

positive psychology approaches and advances in the dominant motivation theory – Expectancy Value Theory (EVT) – which are discussed in the next section.

Advances in Motivational Theory and Research

There is a positive revolution sweeping psychology that emphasizes how individuals get the most out of life, manage to stay healthy and happy in the face of adversity (Craven and Bodkin-Andrews, 2006; Craven and Marsh, 2008). Positive psychology focuses on how healthy, normal, and exceptional individuals can get the most from life; hence positive psychology is the study of optimal functioning that makes life more fulfilling and results in building capability and well-being across the lifespan. The popularity of positive psychology is derived from the research evidence base that focuses on sources of psychological health and well-being as key drivers of multiple desirable outcomes such as adaptive motivation, enhanced performance and academic outcomes, and higher educational aspirations, all of which ultimately contribute materially to societal well-being. However, in order to facilitate the goal of supporting effective intervention within a positive psychology framework, the pathology of maladaptive functioning (e.g., depression, violence, racism, etc.) also needs to be synergistically accounted for; therefore positive psychology research does not preclude inquiries into the negative side of human behavior. Positive psychology approaches have become popular due to criticisms that traditional psychology has focused exclusively on a pathological perspective neglecting the potential of positive self-fulfillment. Instead of concentrating on repairing the damage using a disease model of human functioning, Seligman and Csikszentmihalyi (2000) concluded that an emphasis on the 'disease model' does not enable a focus on how to prevent the problems psychologists aim to cure. Instead, a positive psychology approach would be more powerful in defining effective ways to improve one's well-being by enhancing the self.

Simultaneously, in Australia and throughout the world, there is an increasing emphasis on how to cultivate the well-being and psychological tools of Indigenous peoples (Craven and Bodkin-Andrews, 2006). However, there is a paucity of research on Indigenous populations that could have capitalized on recent advances in positive psychology theory and research. Fresh solutions from a positive psychology perspective are urgently required to address complex issues to successfully cultivate Indigenous students' well-being and address their educational disadvantage. We propose that part of the solution lies in positive psychology approaches that capitalize on advances in motivational theory to result in adaptive Indigenous student motivation that would facilitate schooling engagement, aspirations to participate in higher education, and reaping the benefits thereof. The importance of motivational constructs for education is well demonstrated by Thomson and Hillman (2010) who, based on the Longitudinal Study of Australian Youth (LSAY) extension of PISA 2003, examined the futures of students at age 19 who at age 15 were low achievers. They found that the key predictors at age 15 for long-term success – even controlling for socioeconomic status (SES) – were mathematics motivation, educational and occupational aspirations, enjoyment of school, and a positive school climate. On the basis of these results, they concluded: "The significant influence of motivation on young people's later outcomes is an important message for parents, teachers and policy-makers" (p. 31).

Expectancy Value Theory (EVT), a dominant theory of motivation, explains motivation and decision-making in relation to expectancy of success in a given task (E) and the value of the outcome (V) (Eccles and Wigfield, 2002). Expectancy is conceptualized as a task-specific self-belief about likely success in a future academic task (Eccles and Wigfield, 2002) and is often operationalized as academic self-concept in educational research. Value is hypothesized to have multiple components: importance, interest, usefulness, and cost. Eccles, Wigfield, and their colleagues have been influential motivation theorists for more than a quarter of a century, stimulating research and creating insights into many long-standing real-world problems, leading to fundamental insights into the sociocultural precursors of achievement motivation. Modern EVT has been successful in placing the interplay between expectancy and value into a sociocultural and developmental context. For example, Eccles and Wigfield have noted that EV perceptions are developmental and that educational and employment choices are made in the context of young people's socialization, past educational experiences, and codevelopment with parents, teachers, and peers. As such, EVT provides a useful conceptual framework for understanding student motivation, engagement, aspirations, and long-term outcomes. In the next section, we review some of the emerging motivational research with Indigenous Australians that has begun to capitalize upon these advances in positive psychology and motivational theory and research.

Academic Motivation of Aboriginal Students

Motivation can be conceptualized as students' energy and drive to engage in learning, and is considered to facilitate students' interest and engagement in, and enjoyment of schooling (Craven and Marsh, 2005). Actual academic behaviors that enhance learning (e.g., persistence, on tasks, academic striving behaviors), and achievement are thought to be closely associated with motivation, which is also linked with self-regulation in learning, enhanced academic performance and self-concept, and aspirations for further education (Craven and Marsh, 2005; Eccles and Wigfield, 2002). As such, researchers have advocated motivation as a potentially potent construct for addressing Indigenous educational disadvantage despite only an emerging amount of empirical research with this population (Bodkin-Andrews et al., 2010a), examples of which follow.

In general, some differences were found between Indigenous and non-Indigenous Australian students, but these differences were mostly small (e.g., Yeung et al., 2013). For example, McInerney's (2003, 2008) cross-cultural motivational research program conducted over decades represents a rare sustained program of empirical research that has investigated the structure, measurement, and relation of motivational constructs for Indigenous and non-Indigenous students. In

general, McInerney and colleagues have found little difference between Indigenous and non-Indigenous students' motivational profiles on eight achievement goal dimensions, five achievement goal measures, four sense-of-self measures, and three academic self-concept measures although there were some differences in degree of endorsement. For example, McInerney (2003) examined motivational factors and academic components of self-concept of urban and rural Indigenous and non-Indigenous school students and found that Indigenous students reported significantly higher levels of competition, social power, affiliation, praise, token, social and performance goal orientations, although these variables typically did not predict a range of achievement outcomes for either Indigenous or non-Indigenous groups. More importantly, there were no significant differences on task, effort, social concern, mastery general, global motivation, sense of purpose for education, sense of reliance in learning, positive self-esteem, English self-concept, or math self-concept. Among these, key predictors of a range of achievement outcomes for both the Indigenous and non-Indigenous groups were effort, sense of purpose, mastery general, global motivation, English self-concept, and general self-concept, and there were no significant differences between the groups on these dimensions. The Indigenous students did have significantly lower self-esteem and lower general valuing of motivation, however. These results led McInerney to conclude: "these results tell a positive story regarding the capacity of Aboriginal children to do well at school given the right sort of motivational environment" (2003: 343).

In later research, McInerney demonstrated the important relations of motivation to schooling outcomes. For example, McInerney (2008) found that Anglo Australian, Asian Australian, Lebanese Australian, and Indigenous Australian students all endorsed positive achievement goal motivation constructs, and for all student groups, mastery orientations were positively associated to schooling outcomes. In sum, McInerney's studies over the last two decades with Indigenous Australians have led him to conclude that students even from very remote Indigenous communities have a very similar frame of reference to non-Indigenous students with regard to motivational goals in education. Furthermore, McInerney and King (2013) examined the roles of self-concept and achievement goals in facilitating self-regulation and deep learning strategies for Indigenous Australian ($n = 319$) and Native American high school students ($n = 100$) and found that self-concept was positively related to mastery goals, deep learning, and educational outcomes across both groups and the relations between self-concept and self-regulated learning whether fully or partially mediated through mastery were strong, demonstrating the salience of both for predicting self-regulated learning. This led McInerney and King (2013) to conclude for Indigenous students:

> academic self-concept and mastery goals are critical psychological ingredients that can contribute to optimal learning … as indicated by our results, the strong positive relations between self-concept and positive learning outcomes suggest that educators who are interested in facilitating mastery goal adoption among Indigenous students can draw from the rich literature on improving students academic self-concepts.

Some research has suggested that the largest motivational differences between Indigenous and non-Indigenous groups can be observed across negative motivational constructs such as self-handicapping and disengagement (Bodkin-Andrews et al., 2010a). Bodkin-Andrews et al. (2013) tested the extent to which adaptive and maladaptive motivational constructs, and their relations to educational outcomes, were similar and different for Indigenous Australian ($n = 227$) and non-Indigenous ($n = 1047$) high school students utilizing the Motivation and Engagement Scale – High School (MES) developed by Martin (2009). They found that Indigenous students in comparison to non-Indigenous students had significantly lower levels of self-belief, mastery, and value of schooling, and significantly higher levels of uncertain control, anxiety, failure avoidance, self-handicapping, and disengagement when compared with non-Indigenous students. All 11 factors measured by the MES were significantly associated with at least one schooling outcome for non-Indigenous students, and eight of the 11 had at least one significant association for Indigenous students. These results led Bodkin-Andrews et al. to conclude that Indigenous students may benefit from more adaptive motivational profiles.

Martin et al. (2013) have proposed that academic buoyancy is an important facilitator of academic motivation for both Indigenous and non-Indigenous students. Experiencing academic adversity is theorized to disrupt the motivational processes important for planning and intentions to undertake further education and training. Academic buoyancy is commonly operationalized as a capacity to effectively deal with academic setback, challenge, and adversity (e.g., challenging schoolwork, threats to self-confidence from negative feedback from educators, study pressure, and periods of poor performance). Martin et al. hypothesized that because Indigenous students experience greater academic adversity, academic buoyancy should serve a more salient role in predicting their educational intentions in comparison to non-Indigenous students. They also hypothesized that, because non-Indigenous students do not experience the same extent of educational adversity as Indigenous students, the variance in educational intentions explained by academic buoyancy should not be as large. As such, Martin et al. proposed that academic buoyancy may reduce the higher incidence of academic adversity experienced by Indigenous Australians in comparison to non-Indigenous Australians. They also suggested that academic buoyancy may be associated with positive educational intentions to complete school and engage in further education and training. Martin et al. (2013) examined the role of academic buoyancy in predicting educational intentions for Indigenous ($n = 350$) and non-Indigenous ($n = 592$) Australian high school students. They found that Indigenous students held less positive educational intentions and that academic buoyancy was associated with more positive educational intentions. In addition, the effects of academic buoyancy on educational intentions were found to be stronger for Indigenous than non-Indigenous students. The effects were not significant for junior high students – but they were significant for senior high school students and the effect of academic buoyancy on educational intentions was stronger for Indigenous senior students than non-Indigenous students. These results led Martin et al. to conclude that

academic buoyancy serves a salient role in Indigenous students' educational intentions in senior high school and therefore could be potentially potent to include in psychoeducational interventions.

The above examples evince that recent advances in motivational theory and research are gleaning new insights into research-derived motivational constructs that may inform interventions to seed success in addressing Indigenous educational disadvantage. Self-concept has also been found to be a key aspect of motivation with important implications for Indigenous populations which is discussed in the following section.

Self-concept Research with Indigenous Australian Populations

Academic self-concept refers to one's perceptions about one's academic ability (Craven and Marsh, 2008). Research has demonstrated that academic self-concept is associated with a wide range of adaptive academic outcomes and shares a dynamic and mutually reinforcing reciprocal causal relation with academic achievement (Craven and Marsh, 2008). More importantly, this mutually reinforcing relation is domain-specific such that self-concept in the math domain, for example, influences math outcomes, which also subsequently influence math self-concept; but these mutual relations are specific within the math domain and hence do not transfer to other domains of self-concept (e.g., verbal). Multidimensional self-concepts are also considered to be a powerful component of well-being fundamental to successfully coping with adversity. Self-concepts have also been demonstrated by a body of international research "to impact on a wide range of critical well-being outcomes and serve as an influential platform for enabling full human potential" (Craven and Marsh, 2008: 104). A positive academic self-concept has also been found to influence coursework selection, engagement, intrinsic motivation, subsequent achievement, educational aspirations, and subsequent university attendance (Craven and Marsh, 2008).

Consistent with a positive psychology emphasis, a positive self-concept is valued as a desirable outcome in many disciplines including education. Attesting to this pervasive significance of the self-construct for Indigenous populations and the outcomes that are mediated by it, the NSW Aboriginal Education Consultative Group Incorporated (NSW AECG) notes the failure of education systems to maximize Indigenous children's sense of identity, and to proactively enhance Indigenous children's academic self-concepts so as to ensure that they feel good about themselves (Craven and Bodkin-Andrews, 2006). As such, maximizing self-concept has been proposed as a vital key to unlock Indigenous educational disadvantage (Craven and Bodkin-Andrews, 2006; Craven and Marsh, 2005, 2008). Hence, positive self-belief is valued as a variable that makes good things happen and facilitates the realization of full human potential for Indigenous students. Furthermore, international work undertaken by the OECD has concluded that self-concept needs to be seen alongside with school achievement as an important outcome of schooling. This is because students with a higher academic self-concept are more likely to display better behavior, maintain psychological well-being, and perform well in achievement tests (Craven and Marsh, 2008).

Similarly, Craven and Marsh (2008) claim that enhancing self-concept is a vital goal in and of itself and that self-concept is an important mediating variable that causally impacts on a variety of desirable outcomes including academic achievement. Indeed, many researchers argue that there exists an extensive literature, spanning diverse disciplines and theoretical perspectives, suggesting that high self-concept promotes goals, expectancies, coping mechanisms, and behaviors that facilitate productive achievement and work experiences, and impede mental health problems. Capitalizing on previous advances in theory and empirical research, Marsh and Craven developed a reciprocal effects model (REM) whereby the causal relation between academic self-concept and achievement is conceived as dynamic and reciprocal. In reviewing the available international evidence (see Craven and Marsh, 2008), they found that support for the REM is particularly strong in relation to academic self-concept and school performance whereby increases in specific domains of self-concept lead to increases in associated performance domains and other desirable outcomes and improved performance leads to better self-concepts. These results clearly demonstrate the pervasive significance of the self-concept construct, offer further support for the theory on which this research is based, and affirm that enhancing self-concept has a causal influence on achievement such that enhancing skills alone is not enough; people need also to hold positive self-concepts of their abilities in specific areas. Given recent international research demonstrating the reciprocal effects of achievement and self-concept in academic domains (Craven and Marsh, 2008), Indigenous students may experience double disadvantage in relation to educational academic performance and self-concept. As yet these research advances have not been fully extended to Indigenous students but interesting insights can be gleaned from some of the emerging literature with Indigenous populations in this field.

Craven and Marsh (2005) sought to better understand the nature and structure of Indigenous students' self-concepts and their relation to aspirations and other desirable educational outcomes. The study aimed to characterize Indigenous students' academic and nonacademic self-concepts in comparison to non-Indigenous students; schooling and postschooling aspirations, the relation of SES and academic self-concept to educational outcomes (aspirations, goals for the future, enjoyment of school, attendance, and students' perceptions of their teachers' ratings of their ability), and compare and contrast the pattern of results for Indigenous and non-Indigenous students. They evaluated multidimensional self-concepts, aspirations, ability perceptions, SES, and perceptions of barriers faced in attaining aspirations for Indigenous ($n = 524$) and non-Indigenous ($n = 1149$) Year 7–12 secondary students ($N = 1673$) from urban and rural regions of three Australian States. Marsh and Craven found that Indigenous students, compared with non-Indigenous students, had significantly higher physical, appearance, general self-esteem, and art self-concepts. Indigenous students also had lower academic self-concept (math, verbal, school), peer relations, honesty, and emotional stability self-concept. No significant differences were present for parent self-concept. For both

Indigenous and non-Indigenous students, Craven and Marsh found that a high academic self-concept and high SES are associated with wanting to stay on at school longer, efficacy in achieving future goals, school enjoyment, lower absences, and higher student perceptions of teachers' ratings of ability. Craven and Marsh noted that "these results offer further support for the suggestion that the effects of SES for Indigenous students are partly mediated by academic self-concept" (p. 225) and "imply that academic self-concept may indeed be a potent determinant of a wide variety of desirable educational outcomes" (p. 228). In addition, they noted that since for 7 of 11 facets of self-concept measured, Indigenous students had lower self-concept, and "Given the established importance of enhancing self-concept as a means to advance academic achievement and other desirable educational outcomes, it is suggested that enhancing Indigenous students' academic self-concepts needs to be seen as a priority for intervention" (p. 227).

In regard to aspirations, significantly more Indigenous students in comparison to non-Indigenous students aspired to leave school earlier than non-Indigenous students, reflecting lower retention rates for Indigenous students. Most Indigenous students (37.1%) aimed to get a job after leaving school, whereas most non-Indigenous students aimed to go to university (78.6%), compared with 30.1% Indigenous students. More Indigenous students (24.6%) compared with non-Indigenous students (19.4%) aimed to undertake vocational educational and training postschooling. These results reflect the lower participation of Indigenous students in university education. This pattern of results led Craven and Marsh to conclude that "more effective strategies need to be put in place to assist Indigenous students set and attain higher schooling, future education and employment aspirations" (p. 226). To identify what barriers might impede students from achieving their aspirations, students were asked to rate the extent that they felt nine factors might limit them for achieving their postschooling aspirations (teacher support, family support, absences, achievement, availability of further education facilities, available job opportunities, employer attitudes, career education knowledge they needed to achieve their goals, amount of career advice they had received). Indigenous students in comparison to non-Indigenous students reported higher scores for all nine barriers. Based on these results Craven and Marsh suggested that "a more concerted strategic approach needs to be developed by a diversity of agencies to address barriers Indigenous students perceive as limiting the achievement of their aspirations" (p. 227). Overall, based on the results of this investigation, Craven and Marsh emphasized that: "identifying effective strategies to enhance Indigenous students' self-concepts in specific facets, could prove to be a vital and fundamental key in unlocking Indigenous educational disadvantage" (p. 229). The importance of targeting domain-specific academic self-concepts is also emphasized in the work of Bodkin-Andrews et al. (2010b), who found that across 176 Indigenous Australian students, verbal/English self-concept predicted 7.72% of the variance in English grades, and math self-concept predicted 7.53% of the variance in math grades, over and above the effects of numerous home-educational resources.

Further complicating the issue of potential disadvantages Indigenous students may face is the apparent difference of opportunities in urban and rural school settings. Major concerns for rural Australians include access to educational opportunities, quality of educational provisions, financial issues, and attitudes toward education. Yeung et al. (2013) examined the self-concepts (i.e., school, reading, math, art, and physical abilities), school enjoyment, school participation, and achievement (self-assessment and standardized test) of a sample ($N = 1342$) of Indigenous ($n = 572$) and non-Indigenous ($n = 770$) students from 52 primary schools (Years 3–6) located in rural and urban areas of New South Wales. Employing a 2 (identity: Indigenous vs non-Indigenous) $\times$ 2 (region: urban vs rural) design, they found significant effects of identity for all variables except for art self-concept. For the three academic self-concepts (school, reading, and math), Indigenous students had significantly lower scores than non-Indigenous students. For physical self-concept, Indigenous students had significantly higher scores than non-Indigenous students. However, for art self-concept, Indigenous students did not differ from non-Indigenous students. Indigenous students also had lower scores in enjoyment of school than non-Indigenous students. They also had lower scores in participation than non-Indigenous students. For achievement, Indigenous students had significantly lower standardized achievement scores in both reading and math. Similarly, Indigenous students' self-ratings of school work were significantly lower than for non-Indigenous students. In contrast, the main effects of region were not statistically significant. However, significant identity $\times$ region interaction effects were found in the achievement scores. For reading achievement, Indigenous students in urban schools scored higher than those in rural schools whereas non-Indigenous students in rural schools did better than those in urban schools. A similar pattern was found for math achievement. However, the effect sizes were all very small (all partial $\eta^2 < 0.10$). Therefore, even though there seem to be some subtle differences between Indigenous and non-Indigenous students in urban and rural settings, the authors cautioned that given the small effect sizes, such differences should not be overstated.

Based on these findings, Yeung et al. (2013) concluded that Indigenous students were clearly disadvantaged in terms of academic achievement, and displayed lower school enjoyment, and participation irrespective of region (urban or rural). Yeung et al. also noted that for nonacademic self-concepts the results did not support previous research of a relatively higher art self-concept for Indigenous children based on stereotypical perspectives, but did support previous research demonstrating higher physical self-concept for Indigenous students and lower academic self-concepts. The consistent pattern of Indigenous students displaying lower scores for both achievement and self-concept led Yeung et al. to conclude that Indigenous students were doubly disadvantaged in achievement and self-concept. They also suggested that "the enhancement of both performance in school work and academic self-concepts is a potentially potent intervention to contribute to breaking the vicious cycle of disadvantage experienced by Indigenous students" (p. 420) and "These results imply that school personnel would be well advised to not assume stereotypic differences between Indigenous and non-Indigenous Australian students or assume a great difference between Indigenous students from urban and rural school settings" (p. 405).

To examine the role of self-concept in students' engagement and disengagement in academic work, Bodkin-Andrews et al. (2012) tested structural equation models with longitudinal data obtained from Aboriginal and non-Aboriginal Australian students. The results, with a sample of 264 Indigenous Australian and 947 non-Indigenous Australian high school students, showed that Aboriginal students are more likely to disengage from school, but the causal impact of this disengagement seems to be negated when the causal impact of academic self-concept is also considered. Hence supporting McInerney and King (2013), the Bodkin-Andrews et al. (2012) findings suggest that enhancing academic self-concept may be a useful strategy for addressing patterns of school disengagement that have been repeatedly found for Indigenous Australians.

Summary

This article has outlined that to address the academic disadvantage of Indigenous students, researchers have begun to go beyond the previous emphasis on the socioeconomic disadvantages these students experience and deficit approaches to capitalize upon recent advances in motivational theory and research based on non-Indigenous populations and positive psychology approaches to identify what seeds success. Researchers have started to investigate Indigenous students' motivation, their multidimensional self-concepts, and the drivers of psychological well-being. These new research findings have broadened our knowledge about the disadvantage Indigenous students suffer and have enabled researchers to devise research-derived potentially potent strategies to inform intervention to prevent and address Indigenous educational disadvantage. Indigenous students and non-Indigenous students' motivational orientations and structure of self-concept seem more similar than different which bodes well on extending advances in international motivational theory, research, and practice based on non-Indigenous populations to Indigenous populations. Current research findings also imply that Indigenous students could benefit from more adaptive motivational orientations and less maladaptive orientations, building academic buoyancy, and enhanced academic self-concepts across multiple domains. Overall, it seems important for future theory, research, and practice in Indigenous education research to employ positive psychology approaches and the best available international theory and research to invest in elucidating motivational constructs that seed success and importantly explicate what enables Indigenous people to flourish.

Motivation in Clinical Interventions

Abstract

Motivation is a multidimensional drive state that serves as a foundation for most clinical interventions, whether they are psychosocial, pharmacotherapeutic, or some combination. An essential element of health behavior change and maintenance of healthy behaviors, motivation is affected by extrinsic factors such as environmental contingencies and internal factors that are established by learning history. Models of Stages of Change and choice behavior help explicate motivation as a construct. Motivational interviewing is a contemporary, prevalent, and evidence-based approach to assessing and enhancing motivation in clients and patients in health care and social service settings.

Definitions, Conceptualizations, and Contemporary Issues

Motivation is a multidimensional drive state that can be modified, reduced, or enhanced (Delinsky et al., 2011; Hayhurst, 2013), and has been defined as "the impetus that gives purpose or direction to human or animal behavior and operates at a conscious or unconscious level" (VandenBos and American Psychological Association, 2007, p. 594). It can operate at primary (e.g., hunger) or secondary (e.g., individual interests and goals) levels and is affected by forces that are internal (e.g., physical needs such as sleep) or external (e.g., encouraging comments from a coach while playing in a sporting event). The regulation of various systems (i.e., social, biological, and cognitive) also depends upon motivation (Ryan and Deci, 2000). In behavioral terms, motivation is described in terms of establishing operations, which are procedures or conditions "that [change] the effectiveness of a stimulus as a reinforcer or punisher…" and also includes "drive states within the organism" (Catania, 1991, p. G15).

In health care, including medical, dental, psychological, and other therapies involving clinical interventions, patient or client motivation may be necessary both for positive behavior change (e.g., initiating an exercise routine) and for maintenance of health behaviors (e.g., daily toothbrushing) (Madukwe, 2013). As a hypothetical construct (MacCorquodale and Meehl, 1948), motivation can only be inferred and is not directly observable. The term 'motivation,' a label given to a construct, is known through behavior. It can be influenced by social forces, including interactions, inclusive of a patient or client's relationship with his or her clinician (Madukwe, 2013). In fact, it is argued that it is the duty of the clinician to assess and enhance, if necessary, his or her client or patient's motivation in treatment (Madukwe, 2013), although it may best be conceptualized as a shared responsibility of both the patient or client and the clinician.

Internal and External Motivation

Individuals are driven to act in ways and to be involved in activities that are engaging and reinforcing, and to avoid activities that are disinteresting, unpleasant, or otherwise punishing. Most conceptualizations of motivation regard it as something 'inside' a person, that he or she 'has,' and that a person can activate motivation by one's own choice. An oft-told humorous story illustrates this 'internal' view of motivation: "How many mental health professionals does it take to change a light bulb?" and the answer is: "Only one, but the light bulb really has to want to change." Internal motivation has been described as "the inherent tendency to seek out novelty and challenges, to extend and exercise one's capabilities, to explore, and to learn" (Ryan and Deci, 2000, p. 70). According to Cognitive Evaluation Theory, autonomy, self-determination, and competence are critical for internal motivation (Deci and Ryan, 1985). Individuals who are more internally motivated have been found to report more enthusiasm and confidence related to a task, which may lead to greater persistence, creativity, and improved performance on the task. Internally motivated behaviors and goals are associated with greater overall well-being. These views of motivation are that it is intrinsic or internal to the person.

Another view, which typically is portrayed as an opposite or completely unrelated state, is extrinsic or external motivation, in which people are prompted to act by external demands or pressures. External motivation involves "the performance of an activity in order to attain some separable outcome…" (Ryan and Deci, 2000, p. 71). Environmental contingencies that guide and determine ('motivate') behavior are omnipresent in the natural and social environment. Cold weather 'motivates' people to wear warmer clothing and to put on gloves, caps, and coats. Accolades, diplomas, and access to fulfilling future employment 'motivate' students to perform well in classes. And, icy roadways 'motivate' people to drive automobiles at a lower-than-typical speed for safety reasons. These environmental contingencies are present throughout life, and are an important part of social and emotional development through adulthood. As such, these contingencies create a learning history for the person that motivates behavior far into the future, and which can be considered an 'internal' state, one that arises from 'external' forces.

While internal motivation typically is regarded more positively by the general public and health professionals, and is considered more sustainable, in reality, almost all motivation is a combination of internal and external factors. Nevertheless,

of the many theories and viewpoints of motivation, some of the contemporary ones emphasize that it is closely tied to internal forces. Internal motivation requires a supportive environment to flourish, and external motivation that is too demanding or harsh is unlikely to maintain behavior once the external contingencies are absent. While some external rewards, pressure, and imposed restrictions (e.g., deadlines) can be detrimental to internal motivation (Ryan and Deci, 2000), when properly applied, external contingencies allow a person to learn to complete a task, and then to encounter the (hopefully) positive contingencies that will follow, and maintain the task-completing behavior in the future.

In clinical interventions, it often is the case that external contingencies initially are arranged to prompt behavior, with a planned transition to internal motivation, once the client or patient encounters reinforcement that occurs naturally in the environment. For example, a sticker chart for cooperative play in the classroom, with a planned reward for 80% adherence in a single day, might first be used with an 6 year-old child. Then, once those cooperative play behaviors are established, the external motivation typically is gradually eliminated, as natural reinforcement (e.g., attention and positive comments from peers and teachers) takes hold and maintains the behavior. Contingencies in the environment can be set up by teachers, clinicians, and staff, but also can be arranged by clients and patients themselves to motivate their own behavior. Change as a result of psychotherapy, for example, involves a huge challenge, in that, typically, it involves one hour per week (of 168) of clinician contact with the client or patient. Clinicians work with clients and patients to help them become aware of internal motives (e.g., desire to be physically attractive to others on the part of an adolescent female with anorexia) but often also to arrange their own environment to include contingencies that provide external motivation for behavior change (e.g., completing daily food intake charts that are brought to clinic appointments, with social praise from clinicians for positive steps). At some future point, the external motivation, which may appear artificial at times, can be reduced and then eliminated because natural contingencies arise to maintain the behavior (e.g., positive comments from peers about her appearance), and because the person's learning history then is such that it supports continuing healthy behavior.

Transitioning from externally to internally motivations can be advantageous for maintaining behavior over time. Further, the individual may find that internally motivated behaviors are more rewarding and have more meaning, in that the belief may be that "I am doing it" rather than relying on some external force. This transition appears to be a function of regulatory processes and perceived loci of control; it likely is associated with greater self-efficacy (Bandura, 1997). This change is reinforcing to the individual, who then perceives that he or she has control in regard to achieving goals and finds pleasure in working toward them (Ryan and Deci, 2000).

Ultimately, clinicians typically hope to have patients or clients encounter natural contingencies that promote and maintain positive, healthy behaviors. An inherent challenge, however, is that the reinforcement associated with many health behaviors is distant in time (e.g., weight loss after dietary changes). Understanding how individuals can work toward long-term health goals can be informed by an understanding of choice behavior.

Self-Control

Motivation is, in some respects, an issue of self-control and impulsivity. It is easy (and commonplace) to choose an immediate small reward (e.g., eating a candy bar) over a delayed large reward (e.g., social and cardiovascular benefits of maintaining a healthy weight). Delay discounting is a concept that speaks to the issue of valuing immediate rewards more than those for which one must wait (Rachlin and Green, 1972) and has become an important issue across the fields of psychology, economics, and health. The magnitude of delayed, large rewards and how quickly their value becomes discounted impacts whether one might choose rewards that are more immediate or more distal in time. The amount of delay for more immediate and more distal awards also impacts choice. Self-control prompts choosing the delayed larger rewards over more immediate but smaller ones, while impulsivity promotes selecting more immediate rewards. As an example, delay discounting, along with time perspective, helps to predict various health behaviors in college students, such as use of frequency of exercising, and eating breakfast, as well as tobacco, alcohol, and drug use (Daugherty and Brase, 2010). Clinicians can help clients and patients become aware of contingencies that operate distantly in time, and thereby cultivate motivation to make healthier choices.

Can Rewards Undermine Internal Motivation?

Rewards clearly can motivate behavior in the short term, but what about the long term, and maintaining behavior over time? Concerns have been raised about the use of incentives to motivate behavior (Kohn, 1993), suggesting in part that rewards undermine creativity and intrinsic motivation to achieve well. Kohn (1993) specifically attacks the operant system of behaviorism, involving application of rewards and punishments contingent upon behavior. Reitman (1998) responded to these criticisms, arguing that behavioral approaches are solution-focused and based on empiricism. Citing the work of B. F. Skinner, Reitman emphasizes the need to include naturally reinforcing contingencies in schools (and elsewhere). Moreover, both so-called artificial (or better, constructed) incentives and those which are naturally occurring help produce a learning history in people that allows the continuation, and even evolution, of healthy behaviors. The use of incentives clearly is entrenched in modern life. It is difficult to imagine a functioning utopian society in which everyone regularly goes to work without the promise of, and attendant motivation associated with, paychecks. What may be most important is there is an effort to ensure that motivation for positive, healthy behaviors in clinical settings is learned by clients and patients, becomes internalized, and is responsive to reinforcement that occurs naturally in their environment. Similarly, paychecks may become less important for financially secure people who find other satisfactions in their work.

Motivation, Behavior Change, and Maintenance of Behavior

Changing patterns of behavior can require a significant amount of time, effort, and motivation (Noordman et al., 2012). Maintaining lifelong health behaviors (e.g., wearing seat belts, regular exercising, toothbrushing, and flossing), however, is a significant challenge as well. For some clients and patients, and for some behaviors, change can be relatively easy. Typically, however, changing established behavior patterns, some of which may be lifelong, is extremely challenging and fraught with relapse, frustration, and discouragement. Rather than clinicians incorporating persuasive tactics, Hayhurst (2013) argues that conversation, cooperation, and understanding in clinical settings are more likely to influence the motivation of clients and patients. Some general motivational strategies include removing barriers to treatment and progress, providing choices, decreasing the desirability of maladaptive choices, expressing empathy, providing feedback, establishing goals, and providing assistance toward achieving the specified goals (Madukwe, 2013). Various contemporary approaches provide models of, and strategies for, change and sustainability of health behaviors.

Stages of Change

The process of change by clients, patients, and others has been conceptualized as a cyclical process in which people move back and forth between stages based on their readiness for, and engagement in, the change process (Prochaska and DiClemente, 1984). Moving from no awareness of a need to change, across this sequence people recognize the need to change and begin to understand and then implement what is required to achieve change (Madukwe, 2013). The main stages of change are pre-contemplation, contemplation, preparation, and action, although maintenance and relapse can be considered stages as well (Prochaska and DiClemente, 1984).

The pre-contemplation stage is the point at which people do not recognize the presence of maladaptive behavioral patterns and, thus, have no intention to change their behavior. The contemplation stage occurs when one begins to consider the possibility of needing to change maladaptive behaviors. Deciding how to change, and anticipating and planning to change one's behavior, are the main features of the preparation stage. The action stage occurs when the person initiates the change process. During this stage, the patient or client is best served by significant assistance, support, and encouragement from the clinician. The transition from the action to the maintenance stage occurs when new, more adaptive behaviors are established and the threat of older, more maladaptive behaviors is less frequent. Relapse involves the return to previous, maladaptive behavioral patterns, and occurs predominantly in the maintenance stage (Madukwe, 2013). Relapse prevention is a strategy that is used proactively to provide motivation for patients and clients, even in the face of a lapse involving the previously changed problem behavior (e.g., consuming alcohol). This Transtheoretical Model of Stages of Change helps clinicians identify clients' and patients' awareness of and readiness to change, and so serves as helpful 'barometer' for individually assessing motivation during clinical treatment. An approach, however, that can be used, regardless of a client's or patient's stage of readiness to change, is Motivational Interviewing (MI).

Motivational Interviewing

In regard to assessing, eliciting, and promoting motivation among clients and patients in health care settings, there is no more powerful or accepted contemporary method than MI (Miller and Rollnick, 2013). In health care, there is a zeitgeist of activity associated with MI research and clinical application to numerous health and social problems. MI originally was developed to treat substance abuse and addiction, but thereafter was applied to a diverse array of health-related maladaptive behaviors (e.g., anxiety, depression, suicidality, eating disorders, medication compliance, dieting, exercise, smoking cessation) (Arkowitz and Westra, 2009; Martins and McNeil, 2009). MI is a client- or patient-centered approach for enhancing motivation to change (Arkowitz and Westra, 2009).

A theoretical model of MI emphasizes two active, dual roles of a relational aspect involving clinician empathy and 'MI spirit' as well as MI technical skills on the part of the clinician that are designed to evoke and then reinforce change talk by the patient or client (Miller and Rose, 2009). With the acknowledgment that change can be extremely difficult to implement, and perhaps even more challenging to maintain over time, a core feature of MI is great respect for clients and patients as people, acknowledging their autonomous right to make their own decisions. MI spirit consists of a collaborative, working relationship that attempts to strengthen the patient's autonomy and enhance various ideas for successful change (Arkowitz and Westra, 2009). Miller and Rollnick (2013) add principles of acceptance, compassion, and evocation to the concept of MI spirit. Acceptance is conceptualized as the clinician demonstrating "absolute worth, accurate empathy, autonomy support, and affirmation" toward the patient or client during treatment (Miller and Rollnick, 2013, p. 24), while embodying a compassionate, caring approach. Evocation of ambivalence and motivation highlights the belief that the ability to change one's behavior resides within the person, and not in the clinician or with his or her persuasive powers.

Humanistic in spirit, MI also is behavioral in nature, based on the principles of selective (verbal) reinforcement. Using MI, clinicians selectively reinforce which aspects of the client or patient's communication about change to highlight and draw attention to during sessions. With a positive impact on treatment adherence generally (Chanut et al., 2005), MI can be used to support both psychosocial and pharmacotherapeutic approaches in health care. MI has been shown to be applicable across cultural groups and socioeconomic domains. As an approach, it seems to be most effective with individuals who initiate treatment with lower levels of motivation (Chanut et al., 2005).

What Is MI?

Currently defined as "… a collaborative, goal-oriented style of communication with particular attention to the language of

change, MI is designed to strengthen personal motivation for and commitment to a specific goal by eliciting and exploring the person's own reasons for change within an atmosphere of acceptance and compassion" (Miller and Rollnick, 2013, p. 29). Primarily a guiding style (with following and directing elements as well), MI involves enhancing a client or patient's motivation to change by exploring, highlighting, and ultimately helping them to resolve *ambivalence* about change (Arkowitz and Westra, 2009).

MI can be used as a stand-alone therapy in and of itself, or incorporated before or during another form of treatment (Chanut et al., 2005). More than a discrete therapy alone, MI also can guide a conversational style, as evidenced by the current MI definition by its developers (i.e., Miller and Rollnick). This MI conversational style then can be used in very brief encounters with patients and clients, such as in primary medical care.

MI involves the clinician stepping out of the typical 'expert' role and addresses the 'righting reflex' on the part of the clinician, which involves the tendency to 'jump in' and help, to direct the client or patient and to prescribe needed courses of action, and to immediately provide (or even demand?) solutions that are based on their expertise (Chanut et al., 2005, p. 718). Instead, in MI, the client or patient is viewed as the agent of change and is the one who must come to believe that he or she is capable of changing (Arkowitz and Westra, 2009). MI includes the following technical elements: resolving ambivalence, avoiding provoking resistance to change, eliciting self-motivational statements, enhancing overall motivation and commitment to change, and assisting the client or patient through the process of change (Madukwe, 2013). These elements of MI now are conceptualized within four processes: engaging, focusing, evoking, and planning (Miller and Rollnick, 2013).

Engaging

The concept of engaging the patient or client can be defined as "the process of establishing a helpful connection and working relationship" (Miller and Rollnick, 2013, p. 26). In addition to building a meaningful connection with the client or patient, the process of engaging increases the likelihood that the client or patient will continue to attend future treatment sessions and ultimately change their maladaptive behavior(s) (Miller and Rollnick, 2013). In engaging clientele from an MI perspective, clinicians are leery of trying to focus on a goal of treatment too early in the treatment process or trying to assert too much control in the conversational flow, as these behaviors may lead to detrimental effects on the therapeutic alliance and treatment outcomes. The building and maintenance of a therapeutic alliance is critical for the success of MI in eliciting ambivalence, change talk, and ultimately, changes in behavior (Miller and Rollnick, 2013). The engaging process involves, to a great degree, active listening by the clinician, as a precursor to guiding the development of motivation to change.

Focusing

A "process by which you develop and maintain a specific direction in the conversation about change" (Miller and Rollnick, 2013, p. 27), focusing also can be viewed as "agenda-mapping," in which the clinician and the patient or client determine which direction to move forward in treatment (Miller and Rollnick, 2013, p. 110). This agenda mapping often is utilized when changing direction in treatment, going around an impasse, discussing sensitive topics, clarifying the relative roles of clinician and patient or client, and the patient or client coming to resolution or acceptance in regard to some facet of life (Miller and Rollnick, 2013). The focusing process in MI provides a direction for treatment to move as well as a clarification of the goals, aspirations, or outcomes that are desired by the client or patient.

Considerations in utilizing MI are the patient or client, the setting, and the clinician's skills. The focus on the patient or client pertains to the concerns and problems he or she presents in treatment. The focus on setting pertains to treatment provided for a particular issue in a specific facility (e.g., driving while intoxicated, urgent medical care, psychotherapy for depression in a mental health clinic), which can be limiting in relation to magnitude of effect for both the clinician and the patient or client (Miller and Rollnick, 2013). The focus associated with the clinician's expertise is based upon both MI spirit and technical skills. There can be ethical dilemmas that arise when foci and overall goals of treatment differ between the clinician and the client or patient. The main goal should be to blend the clinician's and the client or patient's beliefs about the focus of treatment to enhance the possibility of achieving positive outcomes from treatment (Miller and Rollnick, 2013).

Focusing involves a continuum of communication styles (i.e., directing, following, and guiding) (Miller and Rollnick, 2013). The directing approach involves the clinician controlling the flow of the session as well as focus of treatment. The following or nondirective approach allows the patient or client's concerns and desires to control the focus of treatment. The guiding approach is a combination of both the directing and following approaches, and involves both the clinician and the patient or client working in collaboration and sharing common foci for treatment.

In relation to the guiding approach, Miller and Rollnick (2013) recommend an 'elicit-provide-elicit' sequence in which the provision of information is alternated with eliciting information from the patient regarding treatment and behavior change. This type of sequencing limits the degree to which the clinician is controlling the session and attempts to increase the frequency with which the patient or client speaks in session. Relative 'talk time' is a crucial component of MI consistency; if the clinician talks most of the time, then the client or patient has little opportunity to talk about ambivalence regarding change, and the emphasis in the clinical encounter is on the practitioner and his or her opinions about what is best for the patient or client. In many instances, the clinician should avoid monologues and speak less (in total time) than the client or patient, although that relative percentage may vary across a treatment session, as earlier in an encounter, the clinician may do more reflective listening, and later may provide more information.

Evoking

This process is "…eliciting the client's own motivations for change…" (Miller and Rollnick, 2013, p. 28), and

incorporates the preliminary stages of planning, in which the client or patient generates ideas, thoughts, and feelings about changing his or her behavior, as well as the process by which change can occur. During this time, clinicians listen for and highlight the all-important 'change talk.' Reinforcing change talk (in part, by reflective listening) increases the likelihood of the patient or client ultimately engaging in actual behavior change. During the process of evoking the patient to change his or her behavior, clinicians resist the 'righting reflex' and uninvited advice-giving, and assist patients and clients in finding their own personal motivation(s) for change. Rather than attempting to instill motivation by persuasion, fear tactics, or other measures, clinicians 'nurture' the patient or client's own motivation and commitment to change through the use of technical MI skills. The evoking process of MI is critical for resolving the patient or client's ambivalence regarding behavior change. The process of guiding the client or patient and evoking his or her own motivation for behavior change is one of the defining features of MI (Miller and Rollnick, 2013).

Planning

The process of planning with the client or patient incorporates confirmation of the commitment to change as well as establishing a specific plan (Miller and Rollnick, 2013). Clinical judgment is required in regard to the appropriate time to move from evoking to planning. In planning, there typically first is recapitulation (a summary of the patient or client's change talk), followed by a key question (a simple, direct question regarding thoughts and feelings pertaining to behavior change at the present time). The planning stage predominately focuses on the specific aspects of behavior change and information seeking and provision. This approach is very different from the clinician asking if the patient or client believes he or she should change his or her behavior(s). Creating the plan for change is only the beginning part of the planning phase of MI; it is an ongoing process that requires re-evaluation as the person begins to engage in behavior change (Miller and Rollnick, 2013).

Foundations and Principles of MI

MI spirit is one of two major crucial components of successful treatment in this approach (Miller and Rose, 2009). More specifically, a basic principle is that clinicians using an MI approach suspend judgment, actively listen during treatment, and communicate respect and acceptance to the patient or client. Madukwe (2013) argues that expressing empathy is one of the most important aspects of MI. Further, it is foundational that a collaborative relationship exists between the clinician and the patient or client, one that is supportive, and that creates a safe and open environment for patients or clients to explore their own ambivalence, and to communicate their concerns and feelings relating to change.

A central tenant of MI is that ambivalence regarding altering one's behavior(s) is a normal part of the change process (Miller and Rollnick, 2013). If a clinician attempts to force the idea of change on the patient or client, it is likely that the he or she may resist or even stop attending treatment (Miller and Rollnick, 2013). Some methods for reducing resistance to and ambivalence about change and 'rolling with resistance' include the use of reflections, shifting the focus of the conversation, and reframing (Madukwe, 2013). Patients and clients often express or display hesitancy in regard to the idea of change unless they have confidence in their ability to successfully achieve change (Miller and Rollnick, 2013). Therefore, another principle is that clinicians support the patient or client's self-efficacy (Bandura, 1997). The clinician can assist in increasing confidence through affirmations recognizing and highlighting the person's strengths.

Some argue that, in addition to self-efficacy, the creation of discrepancy between one's values and current behavior is needed for behavior change (Grave et al., 2013; Miller and Rollnick, 2013). Establishing cognitive dissonance between one's values and current behavior patterns is likely to lead to motivation to change one's behaviors to be more in line with one's values. Seeking clarification and exploring the patient or client's concerns relating to the discrepancy between values and current behaviors is pivotal to behavior change.

In MI, it is necessary to draw attention to and reinforce 'change talk.' This form of communication occurs when the patient or client begins to discuss the possibility of changing maladaptive behaviors. During this process, a decisional balance, in which the client or patient examines the pros and cons of change, can be created and explored (Madukwe, 2013).

Overall, the power to decide to change resides with the client or patient (Madukwe, 2013). Therefore, a goal of MI is to assist patients and clients in resolving ambivalence and committing to changing maladaptive behaviors. In addition to MI spirit and underlying principles and foundations, there are specific skills which constitute the second major component of MI approaches.

MI Technical or Micro-Skills

The major technical therapeutic skills of MI are open-ended questions, affirmations, reflective listening, and summarizing. These technical skills area a primary aspect of the other major component of MI, in addition to MI spirit (Miller and Rose, 2009). Open-ended questions keep the conversation moving forward by encouraging the patient or client to freely share after a prompt that is less structured than, say, a closed-ended question. Open-ended questions also communicate that the clinician is listening to the client or patient's concerns and feelings associated with the pros and cons of change.

Affirmations communicate appreciation, respect, understanding, and validation of the patient or client's concerns pertaining to change. Moreover, affirmations assist in building rapport, the therapeutic alliance, and improving the client or patient's self-efficacy and confidence in the ability to successfully change.

Reflective listening involves clinician attempts to discern and state what patients or clients are communicating, thus making the meaning of their statements more salient (Miller and Rollnick, 2013). This skill also can be utilized to further evaluate the person's statements about change and engage him or her in greater thoughtful consideration of behavior change. Clinicians can incorporate paraphrasing, rephasing, as well as a variety of different types of other reflections (e.g., double-sided reflections) to clarify the meaning of the client or

patient's feelings and concerns. Feeling reflections highlight the client or patient's emotions, whereas simple reflections are a direct restatement of the client or patient's verbalizations. Complex reflections involve a combination of drawing attention to feelings and/or thoughts. Overall, reflective listening assists in identifying ambivalence toward change and resolving it, as well as increasing motivation to change behavior (Madukwe, 2013).

Summarizing statements are organizing tools that can link conversational subjects together, as well as emphasize change talk and reduce ambivalence toward change (Chanut et al., 2005). These summaries can be viewed as a 'long reflection' (Miller and Rollnick, 2013, p. 34). Summarizing statements indicate that the clinician is listening carefully to the person's concerns; they increase the client or patient's degree of cognitive processing pertaining to change. Miller and Rollnick (2013) suggest that summarizing statements also can be incorporated as a transitional tool to move from one MI process to another.

Limitations of MI

Treatment utilizing MI can take extra time with clients and patients (although there are very brief interventions, and an MI conversational style), and require additional resources and training (Chanut et al., 2005). Specifically, clinicians must receive training and supervised practice in MI to be able to recognize cues in session as well as to apply the skills effectively (Chatnut et al., 2005). Depending on the context, clinicians may struggle with "stepping out of the expert role" as suggested by MI, based on their professional instincts and training (Chanut et al., 2005). Regarded as 'simple but not easy' (Miller and Rollnick, 2013, p. 303), MI concepts and skills are readily understood but much harder to implement, particularly in 'real time' during interactions with patients or clients. MI may be unnecessary, or even counterproductive, with clients and patients who are ready to change, or already engaging in change behaviors, as it can seem cumbersome, indirect, and time-inefficient. Finally, certain MI concepts, particularly MI spirit, are diffuse constructs and difficult to define.

Summary and Conclusion

Motivation on the part of the client or patient typically is critical for successful clinical interventions, whether they be taking medicines as prescribed, doing homework assignments to practice relaxation, or assessing one's glucose levels at home. Motivation can be influenced by both internal and external factors, and importantly by a person's learning history. Both intrinsic (internal) and extrinsic (external) factors have been shown to have powerful influences on motivation to change. In addition, motivation has been found to be related to choice behavior, and whether a person engages in self-control or is impulsive in decision making. The Stages of Change theory highlights the importance of motivation in terms of behavior change, emphasizing varying levels of preparedness to change.

Motivational interviewing (MI) highlights the importance of encouraging behavior change in clients or patients during treatment. MI is composed of four processes in which the clinician works collaboratively with the patient or client in developing and maintaining motivation in treatment to ultimately decide upon the possibility of behavior change. MI is composed of many specific clinical methods that encompass a person-centered approach to treatment. Originally designed for substance-use disorders, MI has evolved over the years and has been found to be useful as a stand-alone treatment, as a component added to other treatment modalities, or as guide to a conversational style. The overall success and popularity of MI continues to grow, highlighting its promising nature as a treatment for a variety of problem behaviors.

In summary, motivation is a complex and multifaceted drive state that is affected by a person's learning history and environmental contingencies. Specifically, external conditions and prior learning history affect an individual's motivation during clinical interventions and elsewhere. Motivation is an important foundation for behavior change and maintenance of healthy behaviors.

There is a shared responsibility for both the clinician and the client or patient for motivation to change or to maintain health behaviors. Clinicians cannot ethically eschew their duty to help inculcate motivation, or to blame the patient or client for 'lack of motivation.' Similarly, clients and patients cannot rely solely on powerful others (e.g., health care professionals) to provide motivation, and must act in ways that allow ambivalence about change to be identified and resolved, and to structure environments so that change can be supported. Illusive to find, and challenging to maintain over time, motivation is key to positive outcomes in a broad array of clinical interventions in behavioral and general health care.

Abstract

Millions of children and youth participate in sports and physical activities, such as organized after-school programs, school physical education, and community classes. We review the developmental sport psychology literature on two major determinants of motivational orientations and behaviors in physical activity settings – perceived competence and social influence by parents, coaches, and peers. Studies reveal robust processes and mechanisms of influence that suggest interventions for optimizing self-determined motivation and participation in physical activity. A physically active lifestyle, in turn, strongly contributes to positive developmental and health-related outcomes among youth.

Introduction

Millions of children and adolescents participate in sports and physical activities worldwide (Weiss and Williams, 2004). The voluntary nature and rates of participation strongly suggest that physical activity contexts are motivating, enjoyable, and viewed as a source for promoting adaptive developmental outcomes (Weiss et al., 2012b). We use *physical activity* as an overarching term to include structured settings such as school and community sport programs, school physical education, and movement-oriented classes (e.g., dance, motor development), as well as unstructured settings such as free play, recreational activities, and active transportation (e.g., walking or riding a bike to school). These varying activity contexts accommodate age-related preferences, range of ability levels, desired intensities of involvement, and preferred modes of movement experiences. The majority of studies investigating the developmental significance of sport and physical activity participation have focused on structured settings, which include scheduled practices or lessons, adult instructors, and instrumental goals such as skill improvement, physical fitness, and health and well-being.

Physical activity motivation can be conceptualized in cognitive and behavioral terms (Weiss and Amorose, 2008; Weiss and Williams, 2004). *Motivational orientations* connote an individual's reasons for initiating and continuing activity involvement. From this cognitive stance, motivation can be conceived as *because* answers to *why* questions: (1) *Why* do some youth choose to participate in sports and physical activities while others do not? (2) *Why* do some youth try hard and persevere in learning and performing, while others give up easily or drop out? and (3) *Why* do some youth adopt a 'love of the game' attitude toward involvement, whereas other youth participate primarily for extrinsic reasons? *Motivational behaviors* refer to initiating involvement, continuing participation over time, demonstrating sustained effort while participating, and engaging in degrees of activity frequency, intensity, and duration. Such adaptive physical activity behaviors contribute to a healthy lifestyle and overall well-being. The literature in developmental sport psychology identifies determinants of motivational orientations and behaviors that, in turn, optimize social, psychological, and physical development (Weiss et al., 2012a,b).

We review the literature on physical activity motivation among children and youth with a focus on processes and mechanisms of influence from a developmental perspective. We first identify and briefly summarize theoretical frameworks that have guided empirical studies of youth physical activity motivation. Second, we review and synthesize robust findings on perceptions of physical competence as determinants and outcomes of participation motivation. Third, we summarize consistent evidence-based findings on social relationships and interactions as determinants of youth physical activity motivation, with attention to mechanisms of influence by parents, coaches, and peers. Finally, we identify directions for future research that can inform researchers and practitioners of how to optimize sport and physical activity as contexts for deriving developmental and health benefits.

Theoretical Frameworks Relevant to the Study of Physical Activity Motivation

Early descriptive studies of why children and youth participate in sport and physical activity uncovered three major categories of motivation: (1) to develop or demonstrate physical competence, (2) to attain social acceptance or approval, and (3) to experience fun and enjoyment (Weiss and Amorose, 2008; Weiss and Williams, 2004). These ingredients of participation motivation led researchers to adopt conceptual approaches that highlight *perceptions of competence*, *social influence*, and *positive affect* as determinants of motivational orientations and behaviors. Over the past 30+ years, theories conceived within developmental, social, and educational psychology have been used to guide studies of motivation in the physical domain – notably competence motivation theory, global model of self-worth, expectancy-value theory, achievement goal theory, self-determination theory, ecological systems, and positive youth development (Horn, 2004a; Weiss et al., 2012a,b).

Some theories embrace an explicit developmental approach (competence motivation theory, global model of self-worth, expectancy-value theory, achievement goal theory) and identify age-related cognitive and physical attributes that explain variations in motivational orientations and behaviors (Horn, 2004a). Self-determination theory has been a popular

perspective in recent years, with its broad appeal and applicability of basic psychological needs for competence, autonomy, and relatedness as antecedents of motivational orientations and behaviors (Stuntz and Weiss, 2010). Ecological systems and positive youth development approaches reflect more recent developmentally oriented frameworks and show great promise in understanding determinants of youth physical activity motivation, participation behaviors, and health and well-being (Horn, 2004a; Weiss et al., 2012b).

Theory-driven studies show strong support for the role of *self-perceptions* (self-esteem, perceived competence, self-efficacy) and *significant adults and peers* on motivational orientations and behaviors in sport and physical activity (Horn, 2004b; Weiss et al., 2012a,b). Because the need to demonstrate physical competence and attain social approval and acceptance have pervaded the youth participation motivation literature, it is perhaps not surprising that *perceived competence* has emerged as the most important individual difference factor, and *parent, coach, and peer relationships* have been the most important social-contextual factors related to physical activity motivation. Moreover, developmental variations in perceived competence and relative influence of significant adults and peers reveal important theoretical and practical guidelines for maximizing motivational orientations and behaviors. In the following sections, we synthesize and consolidate the literature across conceptual frameworks to feature evidence-based findings on perceived competence and social influence as determinants of physical activity motivation among youth.

Perceived Competence and Physical Activity Motivation

Perceived competence is a central construct within all theories mentioned earlier that are relevant to the study of motivation in the physical domain. *Perceived physical competence* is key to understanding variations in physical activity motivation and refers to beliefs, judgments, and feelings about one's physical abilities and competencies in general (e.g., athletic, physically fit) or in a particular domain (e.g., basketball, tennis, golf; Horn, 2004b; Weiss et al., 2008). Youths' *perceptions* of their ability to perform physical tasks are more explanatory of motivational orientations and behaviors than are *actual* skill assessments. Thus, studies have focused on *how* youth come to judge their physical ability as lower or higher and *why* self-evaluations may be accurate or inaccurate relative to objective ratings or scores.

Level and accuracy of perceived physical competence vary developmentally as a function of cognitive maturity and social–environmental changes that occur with age (Horn, 2004b; Weiss et al., 2008). During early childhood (3–6 years), children are very optimistic about, and often overestimate, their abilities. This may be due to the concrete nature of their evaluations, an undifferentiated conception of ability, and the sources of information used to judge physical competencies. During this developmental period, sports and physical activities are typically structured in ways that emphasize trying to do one's best, mastering developmentally appropriate motor skills, having fun, and learning to cooperate and play well with others. These contextual features probably explain why young children primarily use simple task mastery, effort, and parental feedback as information sources to gauge their ability (Horn, 2004b).

During middle and late childhood (ages 7–12 years), level of perceived competence declines and accuracy increases (Horn, 2004b; Weiss et al., 2008). Children no longer overestimate their abilities relative to objective ratings but, rather, subjective and objective ratings are more likely to correspond. Changes in level and accuracy of perceived competence are attributed to increased cognitive maturity (e.g., ability to make self-judgments of ability between and within achievement domains), a shift from more task- to ego-involving motivational climates in organized sport, and increased use of peer comparison, peer evaluation, and coaches' performance feedback as information sources to appraise physical ability. These sources make sense, given the highly public nature of structured sports and physical activities, in which social comparison and evaluation are key contributors to reflected and self-appraisals of ability.

Among adolescents (ages 13–18 years), level of perceived competence may decline, remain stable, or increase depending on the frame of reference for self-evaluating physical ability (e.g., move up in competitive level or not make the team; compare to teammates or all athletes in the school district; Horn, 2004a; Weiss et al., 2008). Variations may also occur because adolescents differentiate and integrate a greater number of information sources to assess their physical abilities. Compared to younger peers, adolescents use self-referenced information more frequently (e.g., skill improvement, goal achievement, speed of learning skills), continue to use social comparison and evaluation by adults and peers, and are capable of judging their abilities both *within* a domain (e.g., softball vs martial arts) and *between* achievement domains (e.g., sports vs music). In sum, developmental differences in level, accuracy, and sources of perceived competence explain variations in physical activity motivation.

A robust finding in the youth sport literature is the strong relationship between perceptions of physical competence and cognitive (e.g., perceived control, performance attributions), affective (enjoyment, anxiety), and behavioral (e.g., effort, participation) variables directly related to physical activity motivation (Kipp and Weiss, 2013; Weiss and Amorose, 2008; Weiss et al., 2012a). Youth who favorably evaluate their physical abilities are more likely to ascribe successful performance to controllable factors, enjoy their experiences, persevere in learning new skills, and be more physically active. These attributes, in turn, increase the likelihood of sustaining involvement in physical activity over time and acquiring social, psychological, and behavioral competencies and health benefits (Weiss et al., 2012b).

Level of perceived physical competence is also related to self-determined motivation such as participating for the inherent joy of movement, for confirming one's identity as an athlete or being physically fit, and for attaining health benefits from involvement (Stuntz and Weiss, 2010; Weiss et al., 2012a). Self-determined motivational orientations are characterized by being freely chosen and self-regulated, in contrast to controlling motivational orientations that include participating out of feelings of guilt or pressure by others. Self-determined motivation, in turn, is strongly related to physical activity level, continued involvement, and psychological well-being.

Studies have also shown a direct link between perceived physical competence and motivated behaviors (Kipp and Weiss, 2013; Weiss et al., 2012a). Participants in youth sport and physical education who favorably appraise their physical abilities also exert greater effort in learning and performing, report greater intention to continue participation, persevere when confronted by challenging skills, and are more physically active. Thus, perceived physical competence is an antecedent of self-determined motivation, which in turn is strongly associated with physical activity behavior and health outcomes (Kipp and Weiss, 2013; Weiss et al., 2012a). In sum, perceived physical competence is an important target of intervention efforts to maintain and enhance physical activity motivation.

Several theory-driven intervention studies have shown that physical activity is a valued context for improving youths' perceptions of physical competence (Kipp and Weiss, 2013; Weiss et al., 2012a,b). Interventions have included coach-training workshops on how to provide effective feedback and reinforcement and shape a climate conducive to enhancing perceived competence, and consequently adaptive physical activity motivation. Other interventions have included team-building challenges, cooperative learning, positive youth development, and health-promotion curricula that target strategies within physical activity settings to promote positive self-perceptions and consequently overall well-being. The key to enhancing perceived competence, self-determined orientations, and motivated behaviors reside in the beliefs and behaviors expressed by significant adults and peers as they interact with youth in physical activity settings.

Social Relationships and Physical Activity Motivation

Children and adolescents name many social reasons for and benefits of participating in sports and physical activities, such as making new friends, affirming friendships, feeling part of a group or team, and receiving approval and support by parents, coaches, and teammates (Weiss and Amorose, 2008; Weiss and Williams, 2004). Social interactions and relationships are very important to youth and, indeed, processes and mechanisms of social influence by adults and peers feature prominently in understanding motivational orientations and behaviors in physical activity settings (Stuntz and Weiss, 2010; Weiss et al., 2012a). Theory-driven research on parents and coaches abound, and peer influence is a rapidly emerging area of study in terms of individual processes (close friendship, friendship quality) and group processes (peer group acceptance, leadership, cohesion). We review the knowledge base on parents, coaches, and peers, respectively, relative to youth participants' motivational orientations and behaviors.

Parents

In physical activity contexts, parental influence is especially salient during the childhood years, when children spend more time with and are dependent on parents for resources and opportunities (Fredricks and Eccles, 2004; Horn and Horn, 2007). Parents play a crucial role in their children's motivational orientations and behaviors by expressing beliefs and expectations for performance as well as modeling attitudes and behaviors. Although the nature of the parent–child relationship may change in the transition from childhood to adolescence, parents nevertheless remain important sources of motivation for teenagers and emerging adults.

Fredricks and Eccles (2004) classified mechanisms of parental influence as providers of experience, interpreters of experience, and role models. Parents serve as *providers of experiences* by affording children opportunities to participate, such as signing up for classes or teams, transporting to and from practices and competitions, purchasing equipment and uniforms, and paying club and travel fees. As *interpreters of experience*, parents verbalize beliefs about their child's sport ability, provide feedback that conveys what they think is important (e.g., trying your best vs winning), and express nonverbally their evaluation of performance attempts (e.g., facial expressions, body language). As *role models*, parents influence their children through behaviors such as participating in physical activity, sharing stories of past athletic experiences, volunteering as a parent-coach, and by demonstrating a positive attitude toward and enjoyment of their activity participation. Collectively all three parent mechanisms – providers of experience, interpreters of experience, and role modeling – are essential in shaping youths' motivational orientations and behaviors in sport and physical activity (Fredricks and Eccles, 2004; Horn and Horn, 2007).

In the youth sport literature, these three mechanisms of parental influence overlap and multiple forms of parental beliefs and behaviors have been examined simultaneously (Weiss et al., 2012a). That is, parents who provide opportunities for their child to participate and express confidence about their child's potential to do well in sports are also modeling attitudes and behaviors about the importance of a physically active lifestyle and sport as an achievement domain. The evidence-based research highlights five specific parental behaviors that made a strong impact on children's participation motivation in physical activity: (1) providing social support, (2) conveying pressure to be successful in sports, (3) modeling attitudes and behaviors, (4) expressing beliefs about the child's physical competence, and (5) expressing beliefs about the value of physical activity (Weiss et al., 2012a).

Parental social support can be conceptualized as companionship, informational, instrumental, emotional, affection, and admiration, among others (Horn and Horn, 2007; Weiss et al., 2012a). Types of support vary developmentally, with companionship more prevalent during childhood, and emotional and instrumental support remaining stable over the adolescent years. Robust findings indicate that youth participants who rate mothers and fathers as more supportive of their participation behaviors report greater perceived competence, enjoyment, self-determined motivation, and participation behaviors than those reporting lower parental support (Fredricks and Eccles, 2004; Weiss et al., 2012a). Similarly, parents who are perceived as controlling or pressuring in their actions relative to performance expectations are associated with youth reporting higher anxiety and lower enjoyment, self-determined motivation, and participation behavior. Because youths' *perceptions* of parental behaviors are what drive their motivational orientations and participation behaviors, it is essential that parents are keenly

aware of how their verbal and nonverbal expressions affect children's thoughts, emotions, and behaviors in sport and physical activity.

Modeling is defined as changes in attitudes, emotions, and behaviors as a result of observing others, and *models* are individuals whose verbal and nonverbal behaviors serve as cues for observers' subsequent thoughts, feelings, and behaviors (Weiss et al., 2008). Thus parents' own physical activity behavior, attitudes expressed toward the value of physical activity, past sport experiences, and involvement in their child's experiences by attending games, volunteering, reading about the child's sport, and watching televised sporting events with their child reflect inclusive ways in which parents serve as physical activity role models. When modeling has been broadly defined as the relationship between parental attitudes, emotions, and behaviors with children's physical activity motivation, strong support is attained for parental modeling effects on children's motivational orientations and behaviors (Fredricks and Eccles, 2004; Weiss et al., 2012a).

Parents' beliefs about their child's physical competencies are strongly related to youths' motivational orientations and participation behaviors (Fredricks and Eccles, 2004; Horn and Horn, 2007). Youth who perceive that their parents think they are physically skilled and expect they will perform well in sports report higher perceived competence, self-determined motivation, and physical activity involvement compared to peers who rate their parents lower in competence beliefs. Similarly, parents' subjective value toward physical activity is strongly related to children's ratings of importance, utility, and interest value in physical activity. Children who report that their parents believe being physically active or being skilled in sports is important, useful, and enjoyable also report high value for physical activity and are more physically active than peers who report lower parental value toward sport and physical activity.

The parent–child connection in competence beliefs and value of physical activity is an example where the three mechanisms of parental influence overlap. Children must interpret their parents' competence beliefs about them through observing verbal and nonverbal behaviors, such as frequency and type of feedback, encouraging or discouraging remarks, and demonstrating supportive or unsupportive behaviors (Fredricks and Eccles, 2004; Horn and Horn, 2007). Children's perceptions, therefore, stem from parents serving as providers of experience, interpreters of experience, and role models. Most researchers have interpreted competence belief findings as a parent-to-child pathway – parents express confidence or lack thereof about the child's sport competence and the child internalizes this belief in self-appraisals of ability. However, some research suggests that a bidirectional or reciprocal relationship may exist. That is, children who show interest, aptitude, and confidence in sport may *elicit* in parents an interest in their child's participation, confidence in their child's ability to perform well, and behaviors that motivate the child to continue their physical activity involvement (Weiss et al., 2012a). Thus, just as parents can influence their children's beliefs and behaviors so can children's interests, attributes, and participation choices influence parents' involvement in their child's physical activity pursuits. This reciprocal relationship has the potential to afford both children and their parents of the many benefits of physical activity involvement.

Coaches

Once parents socialize children into sport and physical activity, coaches assume a central motivational role in practice and competitive settings. Informational and evaluative feedback by coaches represent credible sources of information by which children and adolescents alike judge how physically skilled they are, and these perceptions of competence predict motivational orientations and behaviors (Amorose, 2007; Horn, 2008). Coaches remain a powerful source of motivation over the childhood and adolescent years and even beyond for those individuals who continue to climb the competitive ladder.

Over the past 30+ years, numerous studies have focused on the types of coaching behaviors that positively or negatively impact youth physical activity motivation (Amorose, 2007; Weiss et al., 2012a). Based on the varied theories used to study coaches as significant adults on young people's outcomes, Horn (2008) created a model of coaching effectiveness to provide a framework for identifying (1) antecedents and consequences of coaches' behaviors and (2) moderating variables that explain variations in coaching effectiveness. Antecedents of coaching behaviors include the sociocultural context, organizational climate, coaches' personal characteristics, and coaches' expectancies, values, beliefs, and goals. In turn, frequency and types of behaviors coaches exhibit affect youths' perceived competence, motivational orientations, and participation behaviors (effort, persistence, performance). Moderating variables that directly or indirectly influence the coach–youth relationship include participant characteristics (e.g., age, gender, culture), personality (e.g., self-esteem, trait anxiety), and sport type (e.g., individual-team; independent–interdependent).

Horn's (2008) heuristic model characterizes a parsimonious way of integrating theoretical approaches, empirical findings, and methodologies used to study coaching behaviors, and enables a comprehensive review of coach influence and youth physical activity motivation. Theory-driven studies of coaches' influence on motivational outcomes in youth sport have focused on four behavioral mechanisms – feedback patterns, leadership styles, autonomy-supportive versus controlling behaviors, and motivational climate (Amorose, 2007; Horn, 2008; Weiss et al., 2012a). Robust findings for feedback patterns reveal that *contingent* and *appropriate* reinforcement following successful performance attempts, and encouragement combined with technical instruction following skill errors, are associated with child and adolescent participants who report higher self-perceptions, enjoyment, intention to continue playing, and long-term participation and lower anxiety and attrition rates. Coaches' use of punishment following skill errors and nonreinforcement for desirable behaviors are generally related to lower intrinsic motivation and motivated behaviors.

Leadership styles are characterized as decision-making approaches (democratic and autocratic), motivational behaviors (social support and positive feedback), and technical instruction to improve performance (Amorose, 2007; Horn, 2008). Adolescent athletes, who perceive that their coaches use a democratic style of decision-making, are seen as caring about

athletes as individuals, provide frequent and contingent feedback, and competently teach skill techniques, tactics, and strategies report higher perceived competence, enjoyment, intrinsic motivation, and motivated behaviors. Coaches who are rated higher in an autocratic decision-making style are associated with athletes reporting lower motivational outcomes.

Complementary to decision-making styles and stemming from self-determination theory are the constructs of autonomy-supportive and controlling interpersonal styles (Amorose, 2007; Horn, 2008; Weiss et al., 2012a). Autonomy-supportive behaviors include efforts to empower participants with choices within limits, acknowledge input on skills and strategies, and provide participants with opportunities for initiative, self-regulation, and leadership. A controlling interpersonal style consists of using pressure and other coercive means to elicit behaviors, engaging in overly critical feedback as a form of motivation, and emphasizing social comparison as the standard for evaluating performance. Considerable research has shown that youths' perceptions of coaches' autonomy-supportive behaviors are related to higher perceived competence, autonomy, and relatedness and, in turn, optimize self-determined motivation and physical activity behaviors (Amorose, 2007; Weiss et al., 2012a). By contrast, controlling coach behaviors are related to lower satisfaction of psychological needs, self-determined motivation, and rates of continued participation.

Motivational climate refers to the way in which coaches define successful and unsuccessful performance in the sport environment (Amorose, 2007; Horn, 2008). A mastery or task-involving climate is one in which success is defined in self-referenced terms, such as personal effort, skill improvement, and mastering new tasks (i.e., personal bests), while a performance or ego-involving climate is one in which success is defined in norm-referenced terms, such as favorable comparison to others (i.e., being the best). Coaches shape the climate in the way they structure learning experiences, offer participants opportunities for choice and self-regulation, and use criteria for recognizing and evaluating performance. Youth perceptions of coach-created team climates or sport environments show consistent and strong relationships with self-perceptions, affective responses, and motivational orientations and behaviors (Amorose, 2007; Weiss et al., 2012a). Higher mastery climates are associated with greater perceptions of physical competence, enjoyment, self-determined motivation, and participation behaviors, whereas higher perceived performance climates are negatively related to these outcomes.

Coaches and parents represent the most salient sources of adult influence on children's physical activity beliefs and behaviors. Their behaviors convey beliefs about youths' physical ability and potential for future success, which in turn makes an impact on motivational orientations, participation behavior, and developmental outcomes. As youth seek autonomy from adult authority and the closeness and intimacy of friendships, teammates and sport friends contribute above and beyond parents and coaches to physical activity motivation.

Peers

In sport and physical activity, positive peer relationships increase in salience over the childhood and adolescent years. Youth want to feel accepted as part of the team or group and value close personal friendships (Smith, 2007; Weiss and Stuntz, 2004). Social reasons are frequently cited for initiating and continuing participation, and social comparison and evaluation predominate as sources of competence information. These social constructs are intimately related to motivational orientations and behaviors. The context of sport is indeed a social enterprise, as teammates, classmates, and nonsport friends figure prominently in young participants' participation motivation and developmental outcomes (Weiss et al., 2012b).

Peer group acceptance and close friendship are both important constructs in youths' physical activity experiences (Smith, 2007; Weiss and Stuntz, 2004). Feelings of acceptance and being liked by one's teammates are related to higher perceived competence, enjoyment, self-determined motivation, and physical activity behavior. Being good at sports is a consistent index of popularity among boys and girls alike, compared to boy-only findings in earlier research (Weiss and Stuntz, 2004). Social cohesion among teammates is conceptually similar to peer group acceptance and is defined as perceptions of how well team members get along and like each other (Weiss et al., 2012a). Higher social cohesion is related to greater positive affect, intrinsic motivation, and continued participation. Thus, peer group processes are consistently related to physical activity cognitions, emotions, and motivational behaviors among children and adolescents.

Friendship quality or social support is strongly related to youth participants' motivational orientations and behaviors (Smith, 2007; Weiss and Stuntz, 2004). Children and adolescents who report greater companionship, esteem support, loyalty, intimacy, similarity of interests, and emotional support with sport friends experience greater enjoyment, perceived competence, self-determined motivation, and commitment to their activity participation than those who report lower friendship quality (Weiss and Stuntz, 2004). In middle and late childhood, qualities such as companionship, similar interests, and absence of conflicts are more characteristic of sport friendships, whereas adolescents view psychological and behavioral features such as loyalty, intimacy, admiration, and conflict resolution as more prominent (Weiss et al., 1996). By contrast, greater reported conflicts, betrayal, disagreements, and arguments with sport friends are counterproductive to adaptive motivational and health-related outcomes (Weiss et al., 1996).

Observational learning connotes another strong mechanism of peer influence on youth physical activity motivation (Weiss et al., 2012a; Weiss and Stuntz, 2004). Peer models can be similar in age, gender, and other characteristics (sport type, ability level, personality) and thus elicit selective attention by observers to demonstrated attitudes and behaviors. Peer models are effective for informing and motivating others to learn skills, show confidence, persevere, and perform better. For example, in interventions using peer mastery and coping models, observers' self-efficacy, motivation, and physical skills improved from pre- to postintervention, and improvements remained stable in a retention assessment. Several studies have also shown that youth who report having active friends are more likely to be physically active themselves (Weiss et al., 2012a; Weiss and Stuntz, 2004). Thus, friends are important for encouraging adaptive motivational orientations

and behaviors through a variety of processes, such as group relatedness, social support, and modeling.

Studies consistently demonstrate the motivational significance of peer relationships among youth participants in sport and physical activity. Yet, to date, most interventions to promote youth physical activity motivation have targeted curricular and behavioral training for coaches and teachers, and some have employed family-based models as strategies for invoking physical activity behavior change (Kipp and Weiss, 2013; Weiss et al., 2012a). Implementing interventions that focus on peer groups and friendships as agents of behavior change is a promising direction for future research on youth physical activity motivation.

Future Research Directions on Youth Physical Activity Motivation

In the first edition of the International Encyclopedia of Social and Behavioral Sciences, limited research in developmental sport psychology existed for youth physical activity motivation. Now, just over 10 years later, the literature abounds with theory-driven studies of determinants and outcomes of physical activity motivational orientations and behaviors. Still, much more remains to be known about how to encourage and reinforce adaptive forms of motivation to optimize holistic health and well-being among youth.

Our first recommendation is the need for more intervention studies and evaluation of their effectiveness to invoke behavioral change in physical activity settings (Kipp and Weiss, 2013; Weiss et al., 2012a; Weiss et al., 2012b). The current volume of cross-sectional and longitudinal studies demonstrates robust findings for perceived competence and significant adults and peers as contributors to self-determined motivation and physical activity behaviors. A handful of randomized control and naturalistic intervention studies exist, as well as evaluation research of intact programs, that reveal processes and mechanisms whereby positive change in physical activity motivation and behaviors occurs (Weiss et al., 2012b). These studies importantly identify effective theoretical constructs, and targets of intervention that are susceptible, for invoking change in youths' motivational attitudes and behaviors over time. Continued intervention and evaluation studies are needed to infer causal relationships among processes, mechanisms, and behavioral change.

Our review of developmental perspectives on youth physical activity motivation was slanted toward processes and mechanisms that maximize adaptive orientations and behaviors. However, at higher levels of competitive sport, there is evidence of negative developmental and health-related outcomes, such as injury, stress, burnout, low self-worth, and maladaptive social relationships (Weiss et al., 2012b). Intervention research to address these concerns is needed. On a related note, knowledge is limited about the long-term effects of early sport specialization, a phenomenon that has become commonplace over the last decade (Weiss et al., 2012b). Is starting young and focusing on one sport a necessary condition for developing expertise and high-level performance, or do the downsides outweigh the benefits? Is elite performance even a healthy or realistic goal for the majority of youth? Is a sampling approach, whereby youth are afforded opportunities for learning a wide range of fundamental motor and sport skills, more developmentally appropriate and sustainable for remaining physically active across the life span and optimizing physical and mental health? Answers to these questions await appropriate research designs and methodologies.

Finally, we would be remiss not to mention the role of physical activity to battle the childhood obesity epidemic (USDHHS, 2008). School physical education has the potential to be a strong public health agent in the United States, yet many programs have been eliminated and downsized. Only a handful of states require daily elementary physical education and many high schools specify only one semester of physical education to satisfy graduation requirements. Given the potential of schools to foster greater physical activity and associated health outcomes (Weiss, 2011), it may be timely to institute motivational teaching strategies to foster opportunities for recommended daily physical activity. Children and youth of all ages and ability levels go to school, but not all can afford after-school programs and prohibitive fees that some competitive programs require. Schools can play a huge role in motivating youth and providing developmentally appropriate physical activity opportunities (Weiss, 2011). In doing so, schools can contribute enormously to the health and well-being of our nation's youth. Thus, future research that provides even more definitive evidence of the connections among physical activity and academic, social, mental, and physical health outcomes is key to inspiring change in educational policy that brings back greater frequency and quality of physical education programs at all school levels.

Concluding Remarks

Sport and physical activity contexts are unique compared to other achievement contexts such as school, family, and neighborhood settings. Behaviors and performance are on public display and invite social comparison and evaluation of competencies. As such, understanding determinants and consequences of motivational orientations and behaviors is important for ensuring positive experiences and the potential for youth to derive developmental and health benefits. Perceived physical competence and influence by significant adults and peers are consistent and strong contributors to self-determined motivation and physical activity participation, thus identifying them as susceptible targets of intervention. More intervention and evaluation research is needed in school and out-of-school-time programs to make informed recommendations for how to encourage more youth to initiate, continue, and sustain their activity involvement and thereby accrue the social, mental, and physical health benefits from embracing a physically active lifestyle.

Abstract

Grounded in the Eccles' expectancy-value model, we review the literature on how families socialize youths' motivational beliefs and choices. Parental beliefs and behaviors are important precursors to youths' motivation. Parents' beliefs and behaviors are shaped by child characteristics, such as gender, and family characteristics, such as income. Following the review, we provide ideas on future directions for this research.

For years, scholars have tried to understand why people decide to engage in certain endeavors and not others. How do college students select their courses and majors? How do children pick which after-school interests and activities they do? Furthermore, where do youths' motivational beliefs come from? How are they influenced by their immediate surroundings, such as the family? In this article, we provide an overview of how families influence youths' motivational beliefs and a summary of the empirical research to date. First, we outline the Eccles' expectancy-value model, one theoretical model that delineates how families influence motivation. Next, we review the current research on how families either support or undermine motivation. We conclude with recommendations for future research on families and motivation.

Expectancy-Value Model of Achievement-Related Behaviors

Drawing on work associated with decision-making, achievement theory, and attribution theory, Eccles and her colleagues developed the expectancy-value model, a comprehensive theoretical model of achievement-related choices (Eccles-Parsons et al., 1983; see Figure 26.1 for the most recent version). They hypothesized that achievement-related choices would be most directly shaped by individuals' competence beliefs and task values. Individuals' competence beliefs are operationalized as judgments about ones' ability to perform certain tasks, expectations for future success, and self-efficacy. Eccles and her colleagues argue that subjective task value is a function of four components: interest (the enjoyment one gets from engaging in the task), utility value (the instrumental value of the task or activity for helping to fulfill another short- or long-range goal), attainment value (the link between the task and one's sense of self and either personal or social identity), and cost (what may be given up by making a specific choice or the negative experiences associated with each possible choice). According to this model, individuals will select achievement-related activities, such as educational, vocational, and leisure choices, if they have high competence beliefs and task values (Eccles-Parsons et al., 1983).

Box B in **Figure 1** denotes the role that socializers play in shaping youths' experiences and beliefs. Because socializers can include a variety of people, such as teachers and parents, Eccles and her colleagues developed a model that describes specifically how parents can influence their children's achievement-related motivational beliefs and outcomes as shown in **Figure 2** (Eccles, 1993). Beginning at the far left, this model predicts that exogenous, cultural, and demographic characteristics of the family, in combination with specific child characteristics, influence parents' general and child-specific beliefs. In turn, parents' beliefs influence parents' general and child-specific behaviors and practices, which in turn influence children's motivational beliefs and choices. In the next section, we review the current research addressing the various paths depicted in the model.

Child and Family Demographic Characteristics

Families are embedded within a specific sociocultural context. As such, family and parenting processes are shaped by larger cultural norms and expectations that are historically grounded. These broad societal and cultural norms are communicated to youth through more immediate social experiences within the family. Both child characteristics and family demographics determine family and parenting processes.

Child Characteristics

Child gender is one of the central child-level demographic characteristics that filters through the entire expectancy-value model. Gender differences in youths' achievement, engagement, and motivational beliefs are evident when children begin formal schooling and often persist throughout school and even to career selection (e.g., Andre et al., 1999). The early onset of gender differences before schooling suggests that families are an important source of influence.

Parents have expectations of what is appropriate for girls and boys as well as what girls and boys are good at. Parents of sons typically have higher value of traditionally 'male-typed domains' (e.g., sports, math) and believe their child is more skilled in these domains compared to parents of daughters (e.g., Bhanot and Jovanovic, 2005; Fredricks and Eccles, 2005). In contrast, parents of daughters rate their child as more competent in reading than do parents of sons (Bhanot and Jovanovic, 2005; Frome and Eccles, 1998). However, there is great variability in parents' gender-typed beliefs. In fact, other

Figure 1 Expectancy-value Model of Achievement Choices.

Figure 2 Model of Parents Influence on Children's Achievement Related to Self-Perceptions, Values, and Behaviors.

studies fail to document gender differences in parents' perceptions of children's ability in and the importance of math, sports, and reading (Andre et al., 1999; Bois et al., 2002; Frome and Eccles, 1998). It is likely that some if this variability depends on the extent to which parents hold traditional gender role beliefs.

Parents can also be gender-typed in their behaviors. Emerging evidence suggests that parents may differentially socialize their sons versus their daughters based on their behaviors in traditionally gender-stereotyped domains (Lytton and Romney, 1991). For example, in both childhood and adolescence, parents of sons have been found to provide more

opportunities and materials promoting science and sports, which are traditionally male-typed domains, than parents of daughters (Bleeker and Jacobs, 2004; Fredricks and Eccles, 2005). Furthermore, Tenenbaum and Leaper (2003) found that parents provide richer explanations and discussions about science museum exhibits when with sons than with their daughters.

Not only can child gender shape parents' beliefs and behaviors, but it can also influence development by shaping the relations among these indicators. In other words, a separate and equally important question is whether the precursors of children's motivation and outcomes are the same for boys and girls. It is possible that different parent behaviors may motivate boys compared to girls. Or perhaps, the parents' confidence in children (or lack thereof) really matters for one gender but not for the other. If the precursors vary for boys and girls, then it will be necessary for parents to engage in different behaviors to support the motivation and pursuits of their sons compared to their daughters. Emerging evidence suggests that although the extent to which parents endorse certain beliefs or the frequency that parents engage in certain behaviors may vary by child gender, the precursors are similar. Prior research shows that parents' activity-related behaviors have similar associations with both boys' and girls' beliefs and choices (Bhanot and Jovanovic, 2005; Simpkins et al., 2012; Simpkins et al., 2010). Thus, parent support is related in higher motivation for both boys and girls.

Family Characteristics

Family-level demographic characteristics also determine family socialization and youths' motivation and achievement. Two of the key demographic indicators are socioeconomic status (SES) and culture (Quintana et al., 2006). Family SES and culture could affect children's motivation indirectly through the opportunity structures in the child's surrounding environments as well as parents' beliefs and practices.

Children growing up in high-SES families fare better academically and are involved in more organized activities and skill-based informal activities during the after-school hours than are children growing up in lower-SES homes (e.g., Fredricks and Simpkins, 2012). For children to both participate in and succeed at a domain, they need to have available opportunities, as well as the knowledge and ability to take advantage of those opportunities – both of which are more often limited in low-SES families (Simpkins et al., 2013). Not only do such parents have limited resources to implement whatever strategies they think might be effective, they also have to cope with more external stressors than middle-class families living in stable, resource-rich neighborhoods (Furstenberg et al., 1999; McLoyd, 1990). Furthermore, SES differences may also be a result of differences in family norms and values (Lareau, 2003). Middle- and upper-class families are more likely to engage in a variety of behaviors, such as enrollment in organized activities, because they believe that such 'concerted cultivation' helps their children develop the skills and experiences necessary to be successful.

Other research has explored the role of culture in families and motivation. Culture determines what activities and goals (e.g., career choices) are valued as well as determining general parental child-rearing beliefs, theories, and goals (Rogoff, 2003). For instance, traditional gender roles and familism (e.g., family as referent and strong value of family) are two core values within Latino culture. Latino daughters in families with strong traditional gender roles may be less likely to engage in masculine activities, such as sports, and often find it challenging to attend organized after-school activities as they often are more protected and have more familial duties than sons (Simpkins et al., 2013). Cultural values can also shape the general child-rearing environment. Among Latino families, familism predicts higher parental warmth and protects against parents' increased harsh parenting in the face of neighborhood disadvantage (White et al., 2012). Culture defines parental belief systems and family norms and routines (Grusec et al., 2000).

Summary

There are many ways that child and family demographic characteristics affect the development of children's motivation. It is important to note, however, that even though these demographic characteristics have been linked repeatedly to children's school achievement, their effects are almost always indirect, mediated by their association with parents' beliefs, practices, and resources (Benner et al., 2008; Melby et al., 2008). Parenting (e.g., autonomy, consistency in parenting) can override the effects of even the most stressful circumstances (Van Horn et al., 2009). In order to support families, we need more research with diverse populations examining when and how families overcome stressful circumstances.

Parents' General and Child-Specific Beliefs

The Eccles' expectancy-value model integrates parents' general beliefs and their beliefs about their child specifically. As noted in Box C, parents' general beliefs include their value of various pursuits (in general and for particular groups) as well as their general beliefs about child rearing and child development. Examples of parents' general beliefs include the extent to which parents believe ability is innate or malleable and parents' beliefs regarding what is appropriate for boys and girls. In contrast, parents' child-specific beliefs are beliefs about a specific child in a particular domain. These beliefs are child- and domain-specific, such that parents with multiple children may have unique beliefs for each of their children across different domains. For example, parents may believe that their oldest daughter is a highly skilled artist with weaker athletic skills, whereas their younger daughter is a skilled artist and reader. Parents' child-specific beliefs include perceptions of their child's abilities, value of a domain for that child, and goals for that child.

Evidence from several studies suggests that parents' estimates of their children's competencies and value of a domain for their child are important predictors of children's own self-concepts, values, and performance. As one might expect, parents who believe their child is skilled in a domain or value a domain for their child are more likely to have children who believe in themselves and who also value that domain (Andre et al., 1999; Bhanot and Jovanovic, 2005;

Bleeker and Jacobs, 2004; Fredricks and Eccles, 2005; Frome and Eccles, 1998). These patterns have emerged in several studies of math, English, and sports, with some emerging work in music, although parents' value seems to be a less consistent predictor than their perceptions of children's competencies (Eccles and Harold, 1991; McGrath and Repetti, 2000).

How do parents' beliefs shape children's beliefs? Parents' general beliefs are the basis for their child-specific beliefs (Box D) and provide the lens through which they interpret youths' previous performance and aptitude. For example, mothers who believed males are better at math than females (i.e., the general belief) have been found to have lower confidence in their daughters' math abilities (i.e., the child-specific belief) than mothers with less traditional beliefs (Bleeker and Jacobs, 2004). Parents' general beliefs can also change how they view children's actual performance. In a recent review, Yamamoto and Holloway (2010) found that parents' future educational expectations for their child was more closely aligned with children's previous performance if parents believed ability was innate, they trusted the school, and they had high self-efficacy beliefs.

Parents' general and child-specific beliefs are theorized to influence parents' behaviors. Indeed, parents' general and child-specific beliefs have been found to predict their parenting behavior in expected ways (e.g., Eccles, 1993; Goodnow and Collins, 1990; Sigel et al., 1992). Parents, for example, are more likely to support children's cognitive development and academic pursuits if parents believe academics and schooling are important. However, much of this research has focused on academics and on parents' general beliefs (and not their child-specific beliefs). But, do parents' behaviors explain the correspondence between parents' and children's beliefs? The current evidence is limited and mixed. The evidence is more consistent in the leisure domains (e.g., sports, music) than in the academic domains (e.g., math), though only a few researchers have tested this tenet of the model (Bhanot and Jovanovic, 2005; Simpkins et al., 2012). For example, Simpkins et al. (2012) found that mothers' behaviors mediated the link between mothers' and youths' beliefs in sports, music, and math, but not reading.

Summary

Parents hold general beliefs about child development that provide the basis for their beliefs about each specific child across different domains. It is theorized that parents' beliefs in turn shape their behavior. Although scholars have found that parents' beliefs and children's beliefs are linked, there is less evidence that parents' behaviors account for those links. We discuss one reason why parenting behaviors may not be a strong mediator, namely the operationalized parenting behaviors, under the future directions section.

Parent Behaviors

Parents' behaviors are noted in Boxes E, F, and G in **Figure 2**. Parents' behaviors are grouped into three types: general climate and style, modeling, and activity-specific behaviors.

General Child-Rearing Climate and Style

The affective and motivational climate created by parents can influence youths' motivation in direct and indirect ways. One of the most widely studied aspects of general climate is parenting style. In the United States, well-adjusted youth are most likely to have parents who use an authoritative parenting style, which is characterized by appropriate levels of warmth and structure, compared to other parenting styles (Steinberg et al., 1991). However, the meaning and impact of parenting styles varies across ethnic groups, cultures, and neighborhood contexts (Chao, 2001).

Recently scholars have examined other aspects of the general family climate and parenting. One such dimension is autonomy support versus control (Grolnick, 2003). From a self-determination perspective, a sense of autonomy and lack of feeling controlled are crucial for engagement and learning (Ryan and Deci, 2002). Autonomy-supportive parents allow children to explore their own environment, to initiate their own behavior, to take an active role in solving their own problems, and to express their points of view (Raftery et al., 2012). In contrast, controlling parents exert pressure to regulate children's behaviors through commands, directives, or love withdrawal; deny their children chances to solve problems; and ignore their points of view (Pomeranz et al., 2007). A growing body of research demonstrates the benefits of parental autonomy support for children's motivation and engagement (Raftery et al., 2012). Autonomy support seems to be particularly important for low-achieving children (Ng et al., 2004).

The affective and motivational climate, or the general warmth shared by parent and child can also influence the extent to which a child internalizes the teachings and advice from parents (Grolnick, 2003). A negative emotional climate or a controlling environment can alter the influence of parents' supportive behaviors. For example, mothers' academic support actually had negative consequences for youth who did not share a warm relationship (Simpkins et al., 2006).

Modeling

The second type of parenting behavior emphasized in the expectancy-value model is parental modeling. Parents' vocational and leisure pursuits can influence their children's choices through processes associated both with observational learning and with the desire to be like their parents (Bandura, 1997; Eccles, 1993). Although modeling is often cited as theoretically important for children's acquisition of attitudes and behaviors, the empirical support for role modeling is mixed. Some studies show a significant link between modeling and participation (e.g., Kahn et al., 2008), whereas others show no relation (e.g., Fredricks and Eccles, 2005).

There are several possible explanations for these mixed findings. First, in some of these studies, modeling and other parenting behaviors were included within the same regression-based analysis, and parent modeling may be a weak unique predictor relative to other behaviors (e.g., coactivity). Another possibility is that modeling may only be effective when a behavior or activity can be learned by simply watching someone. Modeling may have a weak influence on

activities that are more cognitive in nature and require instruction, such as completing a math problem or reading a book. Furthermore, parents' engagement in these domains in the presence of their children is likely to vary. We have found that few parents play musical instruments themselves or have a music-related career (Simpkins et al., manuscript under review). Parents' engagement in other domains, like sports, may only influence children if they see their parent exercising or have knowledge of these activities.

Activity-Specific Parenting

The third and final type of parent behavior is their activity-specific behavior (see Box G). These behaviors are unique from the other two types in that these behaviors are specifically geared toward a child in a particular domain. Parents can promote children's motivation and participation in a variety of ways. In some ways, parents interact with youth directly. In other ways, parents design or manage children's environments that indirectly influence motivation.

Parent encouragement and participation in an activity together (i.e., coactivity) are two strategies that parents can use to promote children's activity participation. Parent–child coactivity can occur through informal activities at home, involvement in organized activities such as being a coach, and attending a community event together (Simpkins et al., 2010). Parent–child coactivity provides a context for parents to offer verbal encouragement, convey the value of an activity, provide feedback, and both model and teach skills. Talented adolescents and elite adult athletes, artists, and musicians report that parent encouragement and coactivity are two key dimensions of parenting that shaped their pathways (Bloom, 1985; Csikszentmilayi et al., 1993). Other research has found that both parental encouragement and coactivity predict youths' self-efficacy beliefs, perceptions of importance, career interests, and activity participation in both academic and leisure domains (e.g., Fredricks and Eccles, 2005; LeFevre et al., 2009; Pugliese and Tinsley, 2007).

Another way that parents influence motivation is through the provision of resources inside and outside of the home (Furstenburg et al., 1999). Parents structure children's experiences through the provision of toys, equipment, books, and other learning activities in the home. Parents also determine what environments outside of the home to which their children will be exposed by selecting neighborhoods, schools, and activities. According to sociocultural theory, the people and objects in one's environments expose children to particular experiences and value systems (Vygotsky, 1978). Higher exposure leads to children's comfort, engagement, and learning in a domain, as well as coactivity with their parents (e.g., reading a book with their parents). Existing research supports sociocultural theory; studies link provision of materials to higher motivation, achievement, and participation in sports, music, and reading (e.g., Fredricks and Eccles, 2005; Pugliese and Tinsley, 2007; Whitehurst and Lonigan, 2001).

As can be seen in Box G, many of these behaviors are supportive in nature and focus on promoting children's motivation, engagement, and persistence. However, parents can also play a role in discouraging children's pursuit of particular endeavors by either not encouraging them to pursue a domain or by actively discouraging children. For instance, a child is unlikely to engage in sports if parents do not provide any athletic materials or experiences. Parents may also actively discourage their child from pursuing a domain they deem inappropriate because of gender-typed beliefs or that their child is not skilled at. This discouragement may be intentional or unintentional. For instance, parents who tell their daughters that a science activity is for boys may unintentionally discourage their daughters' pursuit of science. Little is known about parents' active discouragement of motivation. One would expect that parents who discourage children's pursuit of a domain should have children who are less likely to pursue that domain unless they receive support from another source (e.g., friends, teachers).

Summary

Specific supportive behaviors alone cannot enhance motivation. They must be delivered in an autonomous fashion and within a relationship characterized by warmth for those behaviors to have the largest positive impact on motivation. In other words, the three types of parenting behaviors noted in the expectancy-value models work together to impact motivation. Parent support may, in fact, deter motivation if the overall climate is negative or controlling.

Future Directions

In sum, a growing body of research supports the paths outlined in the Eccles' expectancy-value model. This research has provided important insights into how parents can both support and undermine achievement motivation. In the next section, we outline some important future directions for research on families and motivation.

Holistic Models of Parenting

The findings reviewed in this article suggest that multiple parent behaviors influence children. However, few studies have adopted a holistic, integrated view of parenting. Instead, much of the research has focused on only one or two behaviors, one parent, and/or one activity domain. This way of decomposing parenting contradicts qualitative research suggesting that families influence children simultaneously through multiple behaviors. For example, Bloom (1985) found that elite athletes, musicians, and artists came from homes that were 'child-centered,' where parents supported children's talents through multiple strategies at the same time. The reality is that parenting is executed in a holistic manner that incorporates multiple strategies and behaviors. Further, parenting in one domain is usually analyzed as separate from other domains, but this does not reflect most families' lives. Family time and resources are not limitless. Parents simply cannot enroll their child in every activity or support their child in every domain. In reality, parents have to weigh the costs and benefits of various activities and supporting their children in different domains. As a result, parents have to make challenging decisions on what to promote and how (Grusec et al., 2000).

Few researchers, however, have adopted such an integrated view of family influences in their work. Moreover, many studies

use regression techniques that assess the unique contribution of each predictor adjusting for the other variables in the model. Such analyses decompose parenting into separate, compartmentalized behaviors when it is the parenting experience in its entirety that influences child outcomes. One method which is better able to capture parenting as a whole is the creation of indexes, which often include a heterogeneous set of indicators that may have a low inter-item reliability, but nevertheless, should be combined in a singular construct because they are all theorized to cause the same outcome (Bradley, 2004). Classic examples include research on cumulative risk (Sameroff et al., 1998), the HOME observational scale (Bradley, 2004), and family involvement in children's education (Jeynes, 2007). Researchers should also consider the use of latent variables in SEM (Simpkins et al., 2012), and cluster analysis to provide a more holistic view of parental influences, which complements the knowledge gained through a traditional regression analysis.

Direction of Influence

Most research, including this article, addresses the influence of parents on children. The thrust of the expectancy-value model is also on how parents influence children. However, parents are expected to adjust their beliefs and subsequently their behaviors based on children's aptitude and experiences (Eccles, 1993). Parents may enroll their child in athletics because they value athletics due to the opportunities it provides for physical activity and developing life-long skills, like teamwork. Once parents find out that their child is not very coordinated and struggles at sports, they may change their value of athletics for this child and not enroll them in future sport activities. Parents may also follow their child's interests. If their child likes animals, they might read more stories on animals, take their child to the local zoo, or watch television shows on animals to sustain their child's interest in biology. Qualitative work suggests that parents support their adolescents in the organized after-school activity they prefer (Simpkins et al., 2013).

Such bidirectional influences of children on parents are depicted in many theories of parenting (Grusec et al., 2000), but have not been widely researched. The socialization of children is not a unidirectional process by which parents simply shape children. Although the influence of children on parents has been at the forefront of research on some areas of development, such as temperament (Bates, 1987), children's effects on their parents have not received as much attention in the field of achievement motivation.

Family Diversity

In this article, we briefly reviewed the research on how SES and culture influence families. Although these two aspects of family diversity have received the most attention, there are other aspects of family diversity that are equally important, such as immigration and ethnicity (Quintana et al., 2006). For example, in 2011, approximately 40 million people in the United States were immigrants (Pew Hispanic Center, 2013). For each aspect of diversity, researchers will need to understand both the strengths and challenges facing families, and how these experiences impact on child motivation and achievement. It will also be important in future research to move away from using these demographic characteristics as grouping variables and instead, to unpack how these characteristics shape families' development (Benner et al., 2008; Melby et al., 2008; Simpkins et al., 2013; Van Horn et al., 2009). All of these aspects that help define diversity among families work in combination to impact development. For instance, immigration history determines, in part, families' cultural orientation, which in turn can influence parents' beliefs about organized activities and youths' participation (Simpkins et al., 2013). Moving forward, it will be important to address how each aspect of family diversity uniquely impacts development as well as how they codetermine development.

Conclusion

In this article, we reviewed the ways in which families can influence youths' motivation using the Eccles' expectancy-value model as an organizing framework (Eccles, 1993). Parenting is a multidetermined process that is grounded in one's larger sociocultural context and circumstances. Although there are consistencies in parenting over time, it can also fluctuate day to day given people's moods and daily demands. In future research, it will be important to use a range of methodological techniques to collected nuanced data that capture changes in parent behaviors over time. Researchers have made great strides in describing such processes and how parenting may influence youth. As noted in the future directions sections, there is also much more work to complete to address salient gaps in our understanding.

Abstract

Research on academic motivation offers important implications for instruction. In this article, we review four current and prominent motivation frameworks that are particularly influential: expectancy-value theory, achievement goal orientation theory, self-determination theory, and social cognitive theory. The basic tenets of each theory are reviewed, as well as recent research that focuses on academic outcomes. Implications for learning and instruction are discussed for each framework.

Motivation is a topic that is of great interest to educators because it is related in important ways to student learning. Motivation is extremely important because students' motivation toward various academic subject domains is related to career and life choices. Nevertheless, although the topic is extremely popular with practitioners, there are many misconceptions about what motivation is, and how it is related to student learning. According to Schunk et al. (2008), motivation is "the process whereby goal-directed activity is instigated and sustained" (p. 4). Motivation has to do with how individuals conceptualize their goals, how they carry out activities to attain those goals, how they persist at working toward those goals, and how they evaluate their performance upon goal completion (or noncompletion). As we will review in this article, motivation is a nuanced topic, wherein a variety of theoretical perspectives lend themselves to an array of recommendations to enhance student motivation and achievement.

One of the particularly important distinctions that motivation researchers have made is the distinction between students' *motivational beliefs* and the ways in which teachers' *instructional practices* affect those beliefs (Midgley, 2002). Specifically, it is now very clear that the instructional practices that teachers use in classrooms affect student motivation in important ways (Anderman et al., 2012). In addition, we also know that there is variation in how students will respond to various instructional techniques; whereas the use of a reward might enhance motivation for some students, the same reward might inhibit motivation in others.

In this article, we review four of the most prominent theoretical frameworks in the study of academic motivation. After briefly reviewing the basic tenets of each theory, we will examine current research findings within each, and then discuss implications for learning and instruction. We have selected four theoretical frameworks that have been the focus of much research over the past decade: expectancy-value theory (EVT), achievement goal theory, self-determination theory (SDT), and social cognitive theory (SCT).

Expectancy-Value Theory

EVTs of motivation have a long history in psychology and education. This work originated in theories and studies put forth by scholars including Atkinson (1964) and Lewin (1935). Most current work is rooted in the work by Eccles and her colleagues (most notably Wigfield) (Eccles (Parsons) et al., 1983; Eccles and Wigfield, 2002; Wigfield and Eccles, 2000).

The model proposed by Eccles and her colleagues presupposes that expectancies and values are both important dimensions that underlie academic (and other types of) motivation. The expectancy component refers to individuals' beliefs about their abilities in particular areas or domains and how well they believe that they will perform in these domains both in the present and in the future. The value component consists of four types of beliefs: beliefs about the importance of a task (attainment value), beliefs about the enjoyment experienced by engaging with a task (intrinsic value), beliefs about the usefulness of a task toward reaching goals (utility value), and beliefs about what one must give up in order to engage with a task (costs) (Eccles (Parsons) et al., 1983; Wigfield and Eccles, 2000).

Numerous studies have examined relations between expectancies and values, the roles of expectancies and values in predicting achievement and behavior, and the development of expectancy and value beliefs and found strong support for the model. In general, expectancy beliefs are predictive of achievement and values are predictive of future behaviors (e.g., the intention to take a future course and actual enrollment in those courses in the future) (e.g., Durik et al., 2006). Results of longitudinal studies also indicate that on average expectancies and values decline as children move into and through adolescence (e.g., Wigfield and Eccles, 2001).

More recently, researchers integrated expectancy-value models with other theoretical frameworks. These studies have enhanced our understanding of the relations between specific types of motivational beliefs, and how those relations predict valued outcomes over time. For example, Hulleman and his colleagues (Hulleman et al., 2008) used EVT, achievement goal orientation theory, and work on interest to examine motivation and achievement across a semester in a college psychology course and among high school students enrolled in a summer football camp. Results indicated that when students began the course endorsing mastery (approach) goals, they were more likely to report both intrinsic value and utility value for the course during the middle of the semester; this in turn was predictive of interest in the course and final grades

(as measured at the end of the semester). Thus over time, achievement values mediate the relation between mastery goals and subsequent interest. In other work, Gray (2014) integrated EVT with optimal distinctiveness theory – demonstrating that STEM-focused high school students (i.e., those selected for specialized academic programs in Science, Technology, Engineering, and Mathematics) place more importance on academic tasks that help them both stand out from (uniqueness), and fit in with (similarity), their classmates.

Implications for Learning and Instruction

Researchers in recent years have begun to develop educational intervention studies framed within EVT. Studies focused on increasing expectations for success have existed for many years and have shown consistent support for the power of increasing expectations for success for subsequent academic performance, particularly among lower achieving students (Schunk et al., 2008; also see discussion later on social cognitive theories). More recently interventions have focused on increasing perceived task value. For example, in one recent study by Hulleman et al. (2010), college students were introduced to a method for solving a math problem, and then asked to write either an essay on the potential relevance (i.e., utility value) of a mathematical task, or an essay about two pictures that they were shown. Participants then were given time to work on a problem set, using the new technique. Those participants who wrote essays about relevance experienced enhanced situational interest, and reported being more likely to use the technique again in the future. These effects were particularly strong for participants who entered the study with low performance expectations.

In another study, 188 adolescents and their parents were mailed several brochures about the value of math and science courses and about decision-making during adolescence (Harackiewicz et al., 2012). Access also was provided to a Web site with information about STEM courses and careers. After 15 months, the mothers of the participants reported more positive perceptions of the value of STEM courses; conversations between participants and their parents about STEM courses increased; and the number of STEM courses in which students enrolled during the last 2 years of high school also increased.

Achievement Goal Theory

Students are driven to achieve for different reasons. According to achievement goal theory, the reasons why students strive to achieve pertain to their standards for judging their own competence (Ames and Archer, 1988; Dweck and Leggett, 1988; Elliot and Harackiewicz, 1996; Maehr and Anderman, 1993; Midgley et al., 1998; Pintrich, 2000a,b). Students consequently orient themselves toward meeting these competence standards. Students who endorse *mastery goals* are concerned with learning, growth, or understanding. In a sense, they are immersed in the achievement task itself and preoccupied with their own expertise within that domain. Students who endorse *performance goals* are concerned with their achievement relative to other individuals, or how competent they appear to others. In other words, they use norm-based standards or other individuals as the referent when measuring their own success (for a review, see Kaplan et al., 2002).

More specific forms of achievement goals may be subclassified under the scope of mastery and performance goals (Elliot, 1999). To the extent that individuals vary in their dispositions to approach success and avoid failure, students may endorse performance-approach goals, performance-avoidance goals, mastery-approach goals, and mastery-avoidance goals. A student with a performance-approach goal orientation therefore strives to demonstrate that she or he is smarter, more high-achieving, or more capable than other students. A student with a performance-avoidance goal orientation strives to demonstrate that she or he is no less smart, no less of an achiever, or no less capable than other students. A student with a mastery-approach goal strives to increase her or his understanding, whereas a student with a mastery-avoidance goal strives to avoid a lack of understanding or a loss of expertise. Mastery-approach goals are associated with positive consequences, such as deep cognitive processing of information performance-approach goals are associated with better academic performance, although some mixed findings exist; mastery-avoidance goals are associated with negative consequences, such as greater text anxiety and worry; and performance-avoidance goals are associated with worse academic performance, surface-level processing, and worry (Elliot, 2001; see chapter on Avoidance and Approach Motivation in this volume).

Recent findings have expanded our understanding of achievement goals and their functionality. Sideridis and Kaplan (2011), for example, assessed whether the endorsement of different achievement goals was associated with different patterns of persistence. Study participants were instructed to engage in a series of achievement tasks, which happened to be unsolvable. Though the time participants spent on task deteriorated with each trial, mastery-oriented students appeared most persistent across a series of tasks, and those who were performance-avoidance oriented, appeared the least persistent. After succeeding during one of the trials, however, performance-approach students appeared to demonstrate the strongest motivational recovery – as evidenced by the time they spent engaging in the task. More generally, Huang (2012) conducted a meta-analysis of 151 achievement goal studies and concluded that mastery-approach and performance-approach goals are associated with higher scholastic achievement, but mastery-avoidance and performance-avoidance goals are associated with lower scholastic achievement.

Madjar et al. (2011) reconceptualized mastery-avoidance goals as a two-dimensional construct. The authors describe *task-based mastery-avoidance goals* as a preoccupation with avoiding the loss of competence, and *intrapersonal mastery-avoidance goals* as a preoccupation with avoiding performing worse than one typically performs. In their research these two aspects of mastery-avoidance goals were differentially related with other achievement goals and student engagement outcomes. In particular, intrapersonal mastery-avoidance goals qualified associations between mastery-approach goals and students' reports of positive affect,

negative affect, and maladaptive strategy use. For two students with weak mastery-approach goals, the student with stronger intrapersonal mastery-avoidance goals is estimated to report more positive affect, less negative affect, and lower use of maladaptive learning strategies than the student with weaker intrapersonal mastery-avoidance goals. This effect is even more pronounced when comparing two students who both have strong mastery-approach goals. The findings of Madjar and colleagues highlight that the combination of intrapersonal mastery-avoidance goals and mastery-approach goals may have positive joint impacts on student engagement in ways that the combination of task-based mastery-avoidance goals and mastery-approach goals do not. In addition to these advances in achievement goal theory, further subclassifications of mastery goals also have been proposed (Elliot et al., 2011) – suggesting that individuals may measure success either by success or failure on a task, or in terms to success or failure relative to one's previous performance.

One explanation for why students' achievement goals may differ from context to context is the motivational climate teachers set in their classrooms (Ames, 1992; Ames and Ames, 1984). Teachers who place a premium on learning, effort, and improvement are promoting a *mastery goal structure* in their classrooms. In these mastery-focused environments, students perceive their classroom culture as one in which constant improvement is encouraged and where mistakes are not seen as an indication of incompetence, but are seen as part of the learning process. Students benefit from mastery-focused learning environments – exhibiting fewer self-handicapping behaviors, greater persistence, more effective metacognitive learning strategies, and adaptive help-seeking behaviors (Elliott and Dweck, 1988; Elliot and MacGregor, 2001; Meece and Miller, 2001; Midgley and Urdan, 2001; Ryan and Pintrich, 1997; Stipek and Kowalski, 1989). Teachers who foster a sense of competition among students, or compare high-performing students with other students in the same classroom are promoting a *performance goal structure*. Generally, performance goal structures are linked with a higher prevalence of unfavorable student outcomes including self-handicapping and academic cheating (E. Anderman et al., 1998; Urdan et al., 1998). In these performance-focused environments, students perceive their classroom culture as one in which a student's worth depends on her or his ability or achievement. Messages conveyed by teachers about mastery and performance thus appear to shape learning outcomes directly, as well as indirectly through students' achievement goals (Anderman and Wolters, 2006).

However, students' perceptions of the classroom motivational climate and the classroom social climate appear to be interwoven. Across four studies, Patrick et al. (2011) found that students' perceptions of a mastery goal structure overlapped substantially with their perceptions of teacher emotional and academic support, and the promotion of mutual respect and task-related interaction. Patrick and Ryan (2008) investigated students' interpretations of mastery goal structure items. After responding to mastery goal structure scale items, students were instructed to provide examples of specific teacher behaviors that supported their Likert responses. Results revealed that teachers' pedagogical and affective interactions with students contributed to perceptions of a mastery-focused classroom environment. L. Anderman et al. (2011) took an inductive approach to understand effective teacher practices in the classroom. Over 4000 students were asked to respond to surveys about the instructional climate of their classroom. Survey responses were used to identify teachers who fostered a supportive instructional climate. Classroom observations revealed that these effective teachers supported students' mastery, built and maintained a rapport with students, and managed the classroom. Relatedly, Turner et al. (2013) found that students' perceptions of mastery goal structure and teacher support converge over the course of a semester. The authors proposed a *Changed Perceptions* model of mastery goal structure in which, over the course of a semester, students' perceptions of mastery goal structure would become integrated with their perceptions of teacher support. After following the same students for 2 years across their transition into middle school, the authors found support for this Changed Perceptions model when students were in elementary school, and replicated these results when the same students were in middle school. What the findings of Patrick and colleagues, L. Anderman and colleagues, and Turner and colleagues share is the conclusion that students do not appear to separate perceptions of a mastery-focused classroom environment from the social climate fostered by the teacher.

Implications for Learning and Instruction

There are practical lessons that goal theory brings to bear on the processes of learning and instruction. As a student's perception of goal structures stems from a teacher's messages about the demonstration and development of competence in her or his classroom, goal structures are messages that are delivered alongside the course content itself. For this reason, practices that encourage certain types of goal structures may be manifest in a variety of academic subject areas, and are not necessarily bound to a particular academic subject. For example, conveying to students that their classroom is a safe place to take intellectual risks is a practice that is transferrable to a variety of content areas. Even in nontraditional academic subjects, mastery and performance goal structures are linked with learning. For example, in the context of health education classes, Anderman et al. (2011) found among other outcomes, that higher student perceptions of mastery goal structure were associated with an increase in knowledge about HIV and pregnancy prevention over the course of a semester, and retention of this knowledge a year later. By contrast, performance goal structure was related negatively to students' HIV and pregnancy prevention knowledge both at the end of the semester and at follow-up. Even beyond traditional academic subjects, it appears that instructional practices that foster perceptions of a mastery goal structure can bear directly on important learning outcomes among students.

In terms of the impact of achievement goals on the learning process, Barron and Harackiewicz (2001) noted that mastery goals – when accompanied by performance-approach goals – may facilitate optimal student outcomes. Proponents of

a multiple goals perspective argue that both types of goals are of practical significance in their own right – with mastery goals being related to the use of adaptive learning strategies, and performance-approach goals being related to achievement (Elliot, 1999; Pintrich, 2000b). Proponents of this perspective have recently demonstrated consistent positive correlations between performance-approach goals and achievement, even when controlling for perceptions of competence and measures of ability (Senko et al., 2011). Although it is true that more research is needed in understanding how individuals represent these two types of goals in their minds at the same time, the multiple goals perspective continues to gain currency in contemporary achievement goal theory research.

Self-Determination Theory

Rewards can undermine an individual's natural curiosity and interest. According to SDT (Ryan and Deci, 2000), humans can be drawn to engage in activities because the activity itself is appealing, enjoyable, and fulfilling. This *intrinsic motivation* is seen as an ideal type of motivation in the sense that there are no contingencies associated with the person's engagement in the activity. However, money, recognition, status, and other rewards can shape human behavior such that the same individual who once might have engaged in an activity due to interest now engages in that behavior because of the benefits that are gained by doing so. Rewards can contaminate intrinsic motivation in the sense that the person's level of engagement in the activity would diminish if she or he were no longer able to receive external benefits for engaging in the behavior (Deci and Ryan, 1985; Plant and Ryan, 1985).

The distinction between intrinsic and extrinsic motivation, at times, may represent a false dichotomy with respect to how human behavior is energized and directed (Ryan and Deci, 2008). *Self-determined motivation* (also referred to as autonomous motivation) is a combination of the intrinsic and extrinsic regulatory mechanisms of interest (intrinsic regulation), internalization (integrated regulation), and values (identified regulation). On the other hand, *controlled motivation* represents behavior that is dictated by emotions imposed by others (introjected regulation), such as pride, shame, or guilt, or extrinsic rewards (external regulation). Self-determined motivation is seen as a higher quality form of motivation than controlled motivation in the sense that the forces driving an individual's behavior are all internal in nature, even if some of these forces are secondary to the enjoyment of the task itself (Ryan and Deci, 2000).

Self-determined motivation can be facilitated by contexts that nurture basic human needs for autonomy, competence, and relatedness (Deci et al., 1991). *Autonomy* refers to an individual's perception of choice (i.e., engaging in behaviors because of her or his own volition). *Competence* refers to beliefs in one's capabilities. *Relatedness* refers to one's interpersonal connections with others. In a classroom environment, SDT explains that students whose needs for autonomy, competence, and relatedness are fulfilled through interactions with others in that context will be more self-determined in their achievement behavior.

Recent SDT research has focused on assessing the synergism of different types of motivations. Vansteenkiste et al. (2009) examined profiles of autonomous and controlled motivation among high school and college students. In the high school sample, the authors labeled students, who were high in autonomous motivation yet low in controlled motivation, the *high-quality motivation* profile. Relative to other profiles, this profile of individuals reported greater cognitive, metacognitive, and behavioral outcomes than students with other motivational profiles. In addition to replicating this pattern in the college sample, the authors also found that college students with this profile also perceived their teachers as higher in autonomy support, structure, and teacher involvement. In a similar study of middle school students, Hayenga and Corpus (2010) examined profiles of intrinsic and extrinsic motivation among middle school students. The authors labeled students, who were high in intrinsic motivation yet low in extrinsic motivation, the *high-quality* profile. Relative to other profiles, students in the high-quality profile exhibited superior academic performance. Results also revealed shifts in profile stability over the course of the academic year – with more students shifting toward poor-quality motivation profiles (low-intrinsic, high-extrinsic motivation) over the course of the academic year. In a related study, Wormington et al. (2012) examined profiles of intrinsic, introjected, and external regulation in a sample of high school students. The authors labeled students who were high in intrinsic regulation relative to their introjected and external regulation the *good-quality* profile, and labeled students who were high in intrinsic, introjected, and external regulation the *high-quantity* profile. Membership in these two profiles was associated with high levels of performance and more extracurricular activity participation. However, students who were members of these two profiles did not significantly differ from one another in terms of academic performance and extracurricular activity participation. The authors explain this finding as an advance in SDT research – contending that controlled forms of regulation may perhaps be adaptive in highly controlled high school environments. Overall, work of Vansteenkiste and colleagues, Hayenga and Corpus, and Wormington and colleagues moves toward a clearer understanding of how other types of motivations may bolster or suppress the effect of intrinsic motivation on positive student outcomes.

Implications for Learning and Instruction

Research under the scope of SDT has implications for the extent to which basic psychological needs jointly affect the extent to which students are driven to learn and are able to achieve. Research demonstrates that students consistently benefit when their needs for competence, relatedness, and autonomy are met. For example, students are more motivated to do homework when their basic psychological needs are fulfilled (Katz et al., 2010). Reviews of research on relatedness indicate that students who perceive stronger interpersonal relationships are more motivated to achieve in school (e.g., Martin and Dowson, 2009). Students are more intrinsically motivated when their competence needs are supported (Schunk and Zimmerman, 2006), but the support of competence should be accompanied by support for autonomy (Niemiec and Ryan, 2009). With

respect to the needs for autonomy and competence, students are more likely to achieve, be engaged, be more intrinsically motivated, and experience less negative affect when these needs are fulfilled (Jang et al., 2009). In addition to these joint effects, autonomy support itself is linked with a host of student outcomes including greater academic motivation, positive emotions, persistence, information processing, well-being, and academic performance (Reeve, 2009).

Social Cognitive Theory

SCT, which was popularized by the work of Albert Bandura, is broad in scope, and encompasses a number of concepts and constructs related to the processes of motivation and learning. The theory emphasizes the social interactions between individuals and various aspects of the environments in which they live. The tenets of SCT are far-reaching; the theory and its correlates have served as the basis for work in education, as well as in numerous other fields including human nutrition (Lubans et al., 2012), exercise science (Fuller et al., 2012), and career development (Zikic and Saks, 2009).

Basic Principles of SCT

There are some core ideas that are central to all aspects of SCT. Whereas some of these are more central to learning and instruction than are others, all represent important components of the theory. A thorough understanding of SCT and its implications for learning and instruction are prerequisite to the development of effective SCT-based interventions.

Triadic Reciprocity

First and foremost is the notion of triadic reciprocity (also known as *reciprocal determinism*). Bandura (1986, 1997) posits that there are three main determinants of human agency: behaviors, personal (internal) factors (including cognitions), and the external environment. Human learning and performance are viewed broadly as functions of the interplay and joint influence of these three determinants.

Bandura (1997) cites *depression* as an exemplar of triadic reciprocity. Specifically, depression can be viewed as being caused by interactions between the environment (e.g., experiencing unpleasant or difficult events in one's life), personal factors (e.g., how those unpleasant experiences are interpreted by the individual), and behaviors (e.g., inability to nurture and develop positive relationships with others, which in turn leads to negative reactions from others, which can exacerbate depressive symptoms).

Self-Efficacy

Self-efficacy is a prominent construct within SCT and is quite similar to the expectancy component of EVT. Individuals who are self-efficacious believe that they can be successful at engaging with specific tasks (Bandura, 1997; Pajares, 1996; Schunk, 1989, 1991; Schunk and Pajares, 2002). Self-efficacy is related positively to academic achievement, the use of effective learning strategies, and effort (Schunk and Pajares, 2009). Self-efficacy beliefs can be focused on highly specialized tasks (e.g., one's feelings of self-efficacy at being able to solve a specific algebra problem), or toward more generalized domains (e.g., self-efficacy in mathematics). Researchers have studied the relations of self-efficacy to valued outcomes in numerous domains, including literacy (Schunk and Zimmerman, 2007), mathematics (Fast et al., 2010), and teaching (Ashton and Webb, 1986; Guskey and Passaro, 1994; Tschannen-Moran et al., 1998).

Observational Learning

An important tenet in Bandura's work is that individuals learn from observing others. We can learn from individuals with whom we interact, as well as from individuals whom we are exposed to through television and other media sources, including social media (e.g., Facebook, Twitter, YouTube, etc.). In a classic study, Bandura and his colleagues (Bandura et al., 1963) demonstrated that when children observed models acting aggressively with a doll, those children were more likely to display similar aggressive behaviors when subsequently presented with a doll.

Implications for Learning and Instruction

SCT offers many important implications for learning and instruction. These implications derive from both theoretical tenets of SCT, as well as from years of empirical evidence drawn from applied SCT research. Particularly important are the implications for learning via technology. The major implications are discussed below.

Learning Involves Interactions between Individuals, within Social Contexts

Referring back to the notion of triadic reciprocity, SCT implies that effective learning and teaching involves considerations of the interplay between behaviors, environments, and personal factors. From a design perspective, it is essential to consider all three of these influences. SCT-based work that has emphasized triadic reciprocity has been useful in many domains, including specific areas such as drug and alcohol education (Sharma, 2005), and in more generalized areas, such as studies of self-regulation in learners (Zimmerman and Schunk, 2004).

The implications for instruction are plentiful, and researchers in recent years have begun to examine SCT and triadic reciprocity in new, technology-influenced learning environments (Joe and Lin, 2008; Lin, 2010). Learners interact (behave) within various contexts (environments), and all learners bring their own personal characteristics (beliefs, attitudes, prior knowledge, etc.) into those situations. Notwithstanding its complexity, a consideration of all three of these contexts can allow for the development of optimal learning and teaching opportunities. In particular, when one considers the vastly growing new areas of learning within online and virtual environments, the notion of triadic reciprocity plays an extremely important role, particularly since the environment is now virtual; indeed, the environment is multifaceted, consisting of the software, the hardware, the form of delivery (e.g., video vs audio), the levels of interactivity that are available, and the settings in which the individuals engage in the online learning (e.g., in their homes vs in classrooms).

Learning is Enhanced when Self-Efficacy Beliefs are Supported

As aforementioned, self-efficacy is a strong predictor of learning and achievement. There has been much research indicating that self-efficacy beliefs can be enhanced, thus improving learning and achievement. In recent years, some of the most exciting work in this area has occurred in the medical field. Researchers have demonstrated that self-efficacy beliefs can be enhanced, and that these changes can lead to improved health outcomes. For example, researchers have demonstrated that the use of peer-mentors with newly diagnosed spinal cord injury patients can improve patients' self-efficacy over the course of the first year after diagnosis (Ljungberg et al., 2011). In other studies, researchers have demonstrated that condom self-efficacy in adolescent populations can be enhanced via interventions (Chen et al., 2012).

One of the most well-researched methods for enhancing self-efficacy beliefs is to encourage learners to set proximal (as opposed to distal) goals. Research indicates that when learners set reachable goals and experience success at reaching those goals, efficacy beliefs are enhanced (Bandura and Schunk, 1981). Initial applications of this research were found in the field of special education, where self-efficacy was enhanced in students with learning disabilities when the students were taught to set proximal goals (Schunk, 1985). In recent years, this basic finding has been applied in other fields, including business administration (Brown and Warren, 2009).

Learning is Enhanced through Observation

Much of Bandura's early work on SCT focused on observational learning. Individuals can learn much from observing others. Researchers have applied this work in important ways in recent years. For example, researchers have demonstrated that observation of others' behaviors can lead to improved safety behaviors (Olson et al., 2009). In addition, research indicates that interventions involving observation and imitation can be used to improve outcomes in patients with schizophrenia (Mazza et al., 2010).

Conclusion

In this article, we have examined four theoretical frameworks that have been used in recent years to study and explain student motivation. Each of these perspectives, and others historically addressed in reviews of motivation research (e.g., Weiner's (1985) attribution theory), offers important implications for the design of instruction. Although it is tempting to think of motivation as primarily residing within the student, self-efficacy beliefs, value for learning, self-determination, and achievement goals are informed by a host of factors – including prior experiences with others in a classroom setting and the instructional practices of teachers. Moreover, the study of motivation and learning is left wanting if not considered as being interconnected with identity processes (Eccles [Parsons] et al., 1983; Kaplan and Flum, 2009) and achievement-related emotions (Eccles and Wigfield, 2002; Pekrun, 2006) – two factors that are implicit in existing motivation frameworks, yet they possess a certain theoretical richness in their own right. A broader understanding by educators of the effects of these variables on students may enhance achievement in important ways, and spark and sustain interest in academic domains that have been identified as areas of high priority (e.g., Science, Technology, Engineering, and Mathematics).

Abstract

Originally, motivation was analyzed as a singular determinant of human thoughts, feelings, and actions. It was quickly recognized, however, that motivation operates in concert with other determinants (e.g., cognition, affect, habits). This insight has allowed the psychology of motivation to progress to a very sophisticated level to answer to the question as to which of the human needs are to be differentiated and how these needs manage to guide and energize people. It has also promoted considering the concept of goals (on top of incentives and expectations) which allowed a better understanding of action control; willpower is nowadays analyzed in terms of the effective (effortful and/or automatic) self-regulation of goal pursuit.

Evolutionary theory and the psychoanalytic study of mental illness always were committed to seeing motivation as a primary cause of behavior, and this is also true of behavioral biology and physiological psychology, as they prefer to think in terms of homeostasis (Cofer and Appley, 1964). When hunger occurs, for instance, behavior is instigated (e.g., finding and eating food) that is instrumental to rectifying the imbalance caused by tissue needs and deficits. The named theoretical perspectives have barricaded the simple insight that behavior can occur under externally applied forces as well (e.g., a shove). Even more importantly, the physical structure of the organism, its sensory and perceptual capacities, its cognitive and motor abilities, and so forth, qualify as causal factors. Even habits, once formed, can be seen as such.

Even though motivation has been considered to be the primary cause of people's thoughts, feelings, and actions in evolutionary theory, psychoanalytic theory, behavioral psychology, and physiological psychology, this is not true for the psychology of motivation. There, motivation is just one cause among others, and the focus is on analyzing aspects of thoughts, feelings, and actions conducive to a motivational analysis. These aspects relate to the energization of responses as well as to their selection and persistent implementation. Answers to these questions have changed over time in line with the adhered-to *metamodel* of human functioning. Starting out with mechanistic models (e.g., learning theory), the psychology of motivation moved on to cognitive models (e.g., attribution theory), and has now arrived at self-regulation models that characterize the human as a flexible strategist when it comes to translating motivation into action.

More specifically, the question of the facilitation and energization of certain responses has been analyzed most extensively by Clark L. Hull (1943, 1884–1952) and Kenneth W. Spence (1956, 1907–67), the classic proponents of learning theory. It was suggested that motivational processes as such (assumed to be rooted in general drive or arousal states) do not necessarily control or guide novel forms of behavior but only invigorate innate or learned associative tendencies. Later on, thoughts, feelings, and actions were often characterized as guided, directed, goal-oriented, persistent, or purposive. Such qualities relate to making different choices, but also to unique short-term or long-term efforts in implementing the choices made. Researchers like John W. Atkinson (1957, 1923–2003) and David McClelland (1955, 1917–98) focused on this issue also suggesting a motivational analysis.

To demonstrate how the concept of motivation has changed in history, we describe how two central issues (i.e., basic needs and action control) have been addressed differently by the traditional and the modern psychology of motivation.

Basic Human Needs

Whereas learning theorists, following the lead of Hull, conceived of need as a general, content-free drive, personality psychologists were eager to put content into the concept of need. Sigmund Freud was rather parsimonious by only suggesting two basic needs, namely the life and the death instinct. William McDougall (1932, 1871–1938) listed 18 basic needs which he referred to as instincts (e.g., curiosity, self-assertion, submission). Henry Murray's *Explorations in Personality* (1938, 1893–1988) contains a catalog of 20 psychogenic needs (e.g., need for nurturance, need for succorance) and Abraham H. Maslow's *Motivation and Personality* (1954, 1908–70) proposed a hierarchy of needs whereby the lower need categories related to deficiency needs (e.g., hunger, safety) and the higher ones to growth needs (e.g., need to achieve, need to realize one's potential).

The named approaches excelled in generating sophisticated definitions and descriptions, but did not provide reliable instruments for need assessment. They also failed to answer the question of which of the many needs are activated in a given situation and how such activation processes run off. Moreover, they did not explore the origins of individual differences in the strength of these needs. In later years, Atkinson (1957) and McClelland (1985) addressed these problems with respect to the need for achievement and the power motive.

Still, the question remained: Which of the many conceivable human needs is the most basic? Baumeister and Leary (1995) have raised this issue by applying criteria such as universality, nonderivativeness, satiation, and substitution. According to their analysis, the need to belong in the sense of forming and maintaining strong, stable interpersonal relationships is suggested to be a most basic need. However, this need seems to be in tension with another basic need, the desire

to distinguish oneself and be different from others, as people are found to compete even with their intimates when it comes to performing well on dimensions that are of high personal relevance (Tesser, 1988). Indeed, the need for high self-esteem has been suggested as the ultimate human motive, because it buffers fear of death which is a consequence of humans being conscious of their mortality. Such awareness engenders abject terror that needs to be managed as it could paralyze the ability to act (Pyszczynski et al., 1997). Most recently, human needs have been explored that relate to the cognitive capabilities of a person: the need for competence and autonomy, the need of engaging in and enjoy effortful reasoning, or the need of finding firm answers to open questions (summary by Gollwitzer et al., 2011).

Other recent research on individual differences in terms of motivational orientations has replaced the need (motive) construct with constructs that describe a general goal orientation, such as personal projects, personal strivings, life tasks, or identity goals. Such personal strivings (Emmons, 1996; Gollwitzer and Kirchhof, 1998) are more limited in scope (e.g., to be a honest person) and can be characterized in terms of expectancies of success, complexity, high verses low level of abstraction, avoidance verses approach orientation, degree of conflict between each other, and integration verses fragmentation. The named parameters of personal strivings have been observed to relate to measures of psychological and physical well-being.

Action Control

Early theories portrayed the human as a machine-like reactive organism compelled to act by internal and/or external forces beyond our control (e.g., instincts, needs, drives, incentives, reinforcers, etc.). Prototypical theories are Hull's learning theory and the reformulations by his students. These theories imply that if one just pushed the right button, motivation would result. There is no room for conscious reflections and attempts toward self-regulation. Instead, motivational forces transmit their energy outside of awareness, establishing a state of balance or equilibrium (referred to as arousal reduction, self-preservation, or need satisfaction).

More modern theories have construed human beings as all-just and all-knowing final judges of their actions. For instance, expectancy-value theories (e.g., Atkinson, 1957) assumed that people choose goals in a rational way, based on the comprehensive knowledge of the probability of goal attainment and the goal's expected value. It is proposed that the subjective probability of success and the incentive value of having performed a task (i.e., pride or shame) conjointly affect task choice, both variables being influenced by the perceived difficulty of the task. Elaborations of this model by Heinz Heckhausen (1991, 1926–88) added further expectation-related concepts (e.g., situation-outcome expectancies), and differentiated various aspects of the incentive value (e.g., extrinsic side effects). Attribution theories (e.g., Weiner, 1992) even proposed that the motivational determinants of a person's behavior are causal explanations of prior action outcomes. People are seen as amateur scientists who systematically explore the causes of their behavior. The type of causes discovered are expected to affect a person's readiness to engage in these or related behaviors by influencing affect and expectations.

The motivational importance of control beliefs has also been analyzed systematically. According to Bandura's (1997) self-efficacy theory individuals may hold the firm belief that they possess the potential to execute (i.e., control) the kinds of behaviors that a given task demands. People acquire such beliefs by reflecting on their own relevant past behaviors, observing the behavior of similar others, being evaluated by significant others (e.g., teachers), and observing their own physiological reactions when challenged by a given task. High self-efficacy beliefs are observed to be associated with choosing aspiring goals, exerting strong effort to attain these goals, and persisting in the face of obstacles and hindrances.

Present theories of motivation go beyond conceptualizing humans as all-just and all-knowing. Rather, human beings are construed as flexible strategists. The focus is on the different tasks a person has to perform when transforming wishes into actions (Gollwitzer, 1990, 2012). When choosing goals, people try to live up to the ideal of being an all-knowing and all-just person by processing all the available information in an impartial manner. However, when the implementation of an already set goal is at issue, people are determined to reach the goal and thus become partial, and the desirability and feasibility of a desired outcome are now seen in the most positive light.

Currently, most research on motivation makes use of the concept of goals (Bargh et al., 2010). One line of goal research focuses on the determinants and processes of goal setting, whereas the other line targets goal implementation. With respect to goal setting, for instance, it has been discovered that people who construe their self as an ideal which they intrinsically desire to attain, set themselves promotion goals focusing on establishing and keeping positive outcomes, whereas people who construe their self as an ought which they feel compelled to reach, set themselves prevention goals focusing on avoiding and getting rid of negative outcomes (Higgins, 2006). Moreover, people can regulate the process of goal setting in a more or less productive manner, by the way in which they think about the future outcomes they want to attain. When the desired future is mentally contrasted with negative aspects of impeding reality (e.g., effectively mastering a writing project is mentally contrasted with obstacles standing in its way), relevant expectations of successfully realizing one's fantasies become activated and used. As a consequence, people form goal commitments in a rational manner (i.e., they show strong goal striving when expectations of success are high but leave the field when probabilities of success are low). When people only dream about positive future outcomes or solely ruminate about the negative reality, however, the respective goal commitments stay moderate irrespective of the level of expectations of success (Oettingen, 2000, 2012).

Regarding the determinants of successful goal implementation, how goals are framed makes an important difference. For instance, when achievement goals are framed as learning goals (i.e., goals geared at trying to learn more about how one can successfully carry out the task at hand) as compared to performance goals (i.e., goals geared at trying to

find out how capable one is), failure experiences are coped with more effectively and thus people are more likely to ultimately reach their goals (Dweck, 1999). But it also matters how goal striving is regulated by the individual. For instance, people can protect an ongoing goal pursuit from distractions by making plans on how to deal with them, or they can plan the details (when, how, and where) of the initiation and execution of the goal-directed behavior ahead of time so that any potentially disturbing self-states (e.g., being tired) can no longer interfere (Gollwitzer, 1999; Gollwitzer and Oettingen, 2011). People can also step up their efforts when hindrances are encountered and turn to substitute goals if increased effort still fails to guarantee goal attainment. Other effective action control strategies relate to the regulation of one's emotions, the perceived attractiveness of the goal, and to creating an environment that offers good opportunities for making progress toward goal attainment (Kuhl and Beckmann, 1994).

This recent revival of research on the self-regulation of goal pursuit (Mischel et al., 1996) is reminiscent not only of the mentalists' analysis of willing (James, 1890, 1842–1910) but also of German will psychology (Ach, 1935, 1871–1946; Lewin, 1926, 1890–1947) before the heydays of behaviorism. William James pointed out that any self-regulation either has to do with strengthening a weak tendency to perform a desired behavior (i.e., issues of the obstructed will) or with weakening a strong tendency to perform an unwanted behavior (i.e., issues of the explosive will). William James' analysis of willing was based on the assumption that behavior can potentially be regulated by a person's resolutions (or intentions, subjective goals), even though in certain situations and at certain times this may be difficult.

Kurt Lewin's (1926) experimental work on the willful control of behavior also offers ideas on how such control may come about, and the same is true for the research of Narziss Ach (1935). Lewin suggested that goals assign a valence to objects and events in people's social and nonsocial surroundings. In Lewin's classic example of a person who intends to mail a letter, a mail box entices the person to deposit the letter much as food entices a hungry person to eat. As needs can be satisfied by various types of behaviors which may all substitute for each other in reducing need tension (e.g., eating fruit, vegetables), many different goal-directed behaviors qualify for satisfying the quasineed associated with a set goal. Lewin's tension state metaphor thus effectively accounts for the flexibility of goal striving.

However, Ach's approach to the analysis of willing was quite different. He assumed that the linking in one's mind of an anticipated situation to a concrete intended behavior creates what he called a 'determination' which in turn automatically triggers the intended action when the specified situation is encountered. The strength of the determination was not assumed to relate to the importance of the person's intention or goal but rather to the strength of the specified situation-response link. Ach's assumption that automatic processes may contribute much to a person's goal attainment is supported by recent findings that the self-regulation strategies of both mental contrasting (Oettingen, 2012) and implementation intentions (Gollwitzer and Oettingen, 2011) unfold their beneficial effects on the basis of automatic processes, as well as the discovery that goal striving can be activated (i.e., primed) outside of a person's awareness by subliminally presenting goal-relevant cues (e.g., cues that relate to goal-relevant activities or goal attainment; Bargh, 2006).

Abstract

Recent developments in life course research have enriched the core principle of human agency, moving past personality-based understandings toward an exploration of the ways that human reflexivity interacts with personality to motivate the bounded selection of life course pathways. We build on literature detailing the roles of self-efficacy, personal control, and optimism to suggest economical ways to conceptualize and measure the mutually intersecting influences of individual motivational dispositions and social structures on people's linked lives and life course pathways.

Life course studies involve an interdisciplinary approach to understanding the multifaceted relationships between changing social contexts and human development (Elder and Shanahan, 2006). Fundamentally, the study of the life course adopts a longitudinal perspective, focusing on the interplay between individual biological and social development within changing historical contexts and institutions. Life course theory refers to a set of orienting principles for research on the interplay of social structure and individual lives, reflecting Mills' (1959) notion of the intersection of history and biography (e.g., Elder, 1998). It is fundamentally interdisciplinary, bringing together theory and research across developmental psychology, social psychology, history, and sociology. The past half century has seen the field grow from a fledgling research enterprise into a perspective that influences research across the social sciences, including fields of health, social stratification, social psychology, and developmental science.

The Life Course and Its Paradigmatic Principles

The life course refers to sequential patterns of age-graded events, societal roles, expectations, and social structures bounded by historical time and location. Intersecting trajectories, including marriage, work, education (see Mortimer and Shanahan, 2003) form the backdrop for the contemporary life course. Trajectories involve expected sequences of roles and states (e.g., employed), with some following strongly patterned routes and others involving turning points, redirections of one's life based on circumstances, beliefs, or behaviors. Fundamental to the perspective is that such trajectories are shaped and interpreted by people and institutions within historical eras; the perspective tends toward skepticism about 'timeless' rules of human organization in favor of contextualized understanding of developmental processes and socially structured institutional and cultural influences.

Since its inception a half century ago, the study of the life course has cohered around five general principles that focus less on cohorts and more on individual choices made within historical and social contexts (see Elder et al., 2003): (1) life span development, (2) agency, (3) time and place, (4) timing, and (5) linked lives. We briefly discuss each of these in turn, with an extended discussion of agency later in the article.

The principle of life span development extends the typical focus on childhood development and socialization across the life course. Major changes in individual orientations, physical and mental health capacities, role occupancy, and geography occur throughout one's life. For example, McLeod and Kaiser (2004) demonstrate how early behavioral and emotional problems in children lessen the likelihood of receiving a high school degree and enrolling in college, thus contributing to the reproduction of socioeconomic disparities.

Individual lives are embedded within particular historical eras and locations. While this may appear to be a banal observation, it is often ignored within social science theory and research. The meaning attached to particular transitions or historical events shifts based on era or location; the founding of America means something different depending on one's ancestral history.

Experiences differentially affect individuals based on when they occur within their life course (George, 1993), or the age of an individual experiences a more global event. Elder (1974 [1999]) demonstrates how life course timing informs understanding of how different age cohorts experienced the Great Depression. Younger children experienced more family disruption and difficulty than children who were slightly older, influencing developmental and life course pathways.

Finally, the principle of linked lives explicates the notion that people's lives are lived interdependently through important pairings and social networks. While many statistical models focus exclusively on the individual, in practice, people's life choices are fundamentally shaped by social ties, relationships that can even serve as turning points away from criminal careers (e.g., Sampson and Laub, 1993).

The Emergence of Life Course Theory: An Introduction

Life course theory emerged in response to the growth of longitudinal studies and their conceptual challenges during the last half of the twentieth century (Mortimer and Shanahan, 2003). The challenges called for the replacement of child-based accounts of development with life span concepts and

the contextualization of development over time in an ever-changing society (Elder, 1998). Social roles in relation to the temporal meanings of age have provided this contextual perspective on the social life course of individuals and their development. Age locates people in history through birth year and across their lifetime through age at key life events and transitions, such as first full-time employment. Life course studies now appear with increasing frequency in the social, behavioral, and medical sciences.

These conceptual developments resulted in a life course perspective on Californians who were born at the opposite ends of the 1920s – the Oakland and Berkeley study members (1920–21, 1928–29 birth cohorts) (Elder, 1974[1999]). They experienced hard times in the Great Depression as adolescents and young children, and were followed through the World War II into the postwar era up to the 1970s. These "Children of the Great Depression" were influenced by exposure to hard times in ways that frequently shaped their lives. Conceptual themes from this study depicted key elements of people's lives beginning with a perspective on 'development and aging as lifelong processes.' Their lives were 'linked' to others from family and friends to coworkers. The 'timing of events and social roles,' whether younger or older, in the Depression and World War II, had much to do with the impact of those times on their lives. The 'historical time and place' of the study members profoundly influenced their lives, typically through the choices made and options foregone. These choices were characterized as expressions of 'human agency.'

The central themes of this early study have been reaffirmed in subsequent research as core principles of the life course paradigm. Support for the principle of life span development comes from research that shows the relevance of prenatal development for health in the later years (Kuh et al., 1997). The British national longitudinal studies of birth cohorts (Ferri et al., 2002) are documenting the relationship between the formative years of development and late-life adaptation. The principle of linked lives is expressed through the influence of significant others, whether parents or siblings, close friends or siblings. Laub and Sampson (2003) have shown that wives played an important role in terminating a husband's criminal career.

The principle of life course timing provides insight concerning life chances. Boys who are involved in delinquent activity at an early age tend to persist in this behavior, well into the adult years. Biological dispositions may play a role in this pattern as well as an entrenched life of crime (Moffitt et al., 2002). The principle on historical time and place indicates access to types of life opportunity and risks of disadvantage. Men in the 1920–21 birth cohort of Oakland Study males were exposed to the risks of both Depression hard times and combat in World War II. Very different opportunities and risks were relevant to the male birth cohort of 1940–41.

No paradigmatic principle is more fundamental to the life course and motivation than that of human agency (Haidt and Rodin, 1999). The transition from one activity to another across the life course involves individual initiatives, as well as situational constraints and opportunities. People make choices in life that enable them to exert a degree of control over their life course. In economically deprived families during the Great Depression, young people were confronted by pressing household needs. Some assumed more responsibility over the care of younger brothers and sisters while mother held down a part-time work, while others performed jobs in the community. The employment of mothers illustrates the process by which choices result in 'building a new life course.' No life course is totally shaped by social constraints.

The Agent in Life Course Theory

The problem of understanding individual volition is peculiar to disciplines that typically focus on structural and cultural constraints that enable human action; the issue of 'agency' is only a problematic for scholars that exclusively emphasizes the power of macrosocial forces in shaping observed regularities in human conduct. In the sociological literature, the discussion is often pitched at a level of abstraction that is difficult to translate into empirical research (Hitlin and Elder, 2007). However, notable treatments incorporate the ongoing nature of time into definitions of human agency (e.g., Emirbayer and Mische, 1998; Mische, 2009). For the purposes of this discussion, we bracket those scholars (Loyal and Barnes, 2001; Meyer and Jepperson, 2000) who suggest that human agency is epiphenomenal or sociologically trivial.

In general, the principle of agency suggests the importance of personal factors and choices in the selection and maintenance of various life trajectories. People construct their own courses within social constraints, what Shanahan and Hood (1998) refer to as 'bounded agency.' People navigate their lives as they encounter obstacles and opportunities. Some scholars (e.g., Heinz, 2003; Honneth, 2004) suggest that the modern life course offers greater structural potential for individuals to shape their own life course trajectories.

That individuals make choices is largely unproblematic as social analysis; the devil is in the details. Empirical treatments of agency, less commonly merged with theoretic treatments of the concept, diverge in their focus but can generally be seen to cohere around a few core ideas of individual capacities dealing with potential control over one's life course. Such capacities to exert agency can be subdivided into two broad approaches: (1) a focus on personal skills/attributes that allows people to exert control over their lives and (2) self-beliefs about the possession of those skills (Hitlin and Long, 2009). Prominent life course treatments have focused on both aspects. Shanahan and Hood (1998) hold that a fully specified model of agency requires measurement across multiple dimensions, relationships, and proximal settings that facilitate and mold goal pursuit and macrostructural contexts.

Most notably, Clausen's (1991, 1993) work demonstrates the importance of particular constellations of skills and orientations early in life for understanding later life course outcomes (see also Shanahan et al., 1997). This notion of 'planful competence' draws on psychological Q-sort techniques of members of previously mentioned Berkeley and Oakland studies, rating children on six dimensions combined to assess their skills of self-reflexivity, dependability, and self-confidence. This construct measures how well individuals can make (and adhere to) long-term plans (Shanahan et al., 2000). As Clausen and others demonstrate, young people with more

of these skills evidence more stable work and marital careers and are more capable in dealing with personal setbacks.

A number of related social psychological constructs cohere around the second notion of agency, the motivated significance of self-beliefs in understanding individual pathways across the life course (see Gecas, 2003). From the sociological side, commonly utilized measures include the notion of 'personal control' (e.g., Mirowsky and Ross, 2003, 2007) and 'mastery' (Pearlin, 1983). Psychological traditions offer notions of 'locus of control' (Rotter, 1966) and 'self-efficacy' (Bandura, 1982, 2008; see Gecas, 1989, for sociological appropriations of the construct). Differences exist between these constructs, primarily at the level of scale construction (for an extended discussion of the empirical measures we discuss, see Hitlin and Long, 2009; also Haidt and Rodin, 1999), but they largely agree that individuals carry personal assessments about their ability to persevere in the face of obstacles and influence the events of their lives. A range of studies demonstrate that the possession of higher levels of these beliefs is advantageous for life course outcomes (see Gecas, 2003; Sharkey, 2006; Wheaton, 1980; Christie-Mizell and Erickson, 2007; Frazier et al., 2011; Reynolds et al., 2007), including serving as a buffer between negative life events and individual functioning (e.g., Pudrovska et al., 2005). The ability to persevere in the face of obstacles is itself a social force leading toward advantageous outcomes (e.g., Duckworth et al., 2007). Aging can serve to reduce the sense of agency that people experience (e.g., Pearlin and Schooler, 1978; Schieman and Turner, 1998).

Life Course Motivation

Individuals have a variety of motivations as they navigate the culturally defined sequence of age-graded roles that defines the life course. Chiefly, they are motivated to experience belongingness or relatedness, self-esteem, self-efficacy or competence, autonomy, and a consistent sense of self (e.g., Bandura, 2008; Deci and Ryan, 2000; Leary, 2007).

A consistent sense of self is provided in part through the routine performance of identities associated with social roles and statuses (Owens et al., 2010). Recent advances in life course research have drawn attention to consistency among multiple identities as an antecedent of life course outcomes and as a motivator of life course trajectories. Benson and Elder (2011) performed a cluster analysis of subjective age and psychosocial maturity using nationally representative data, finding support for a pseudo-adult identity type, which is marked by a relatively high subjective age coupled with lower levels of psychosocial maturity; in contrast, an anticipatory adult identity type is marked by levels of maturity that notably exceed subjective age. These inconsistent identity types may well configure role and mental health trajectories in the middle years as adulthood proceeds (e.g., Foster et al., 2008). However, this remains an open area for research. Wang et al. (2012) similarly characterized status inconsistencies among young adults, focusing on mismatches among socioeconomic status, cognitive ability, and high school grade point average in high school. Certain types of mismatches predicted enrollment in the military; military enrollment, in turn, enhanced the attainment of some level of higher education relative to nonveterans with the same status configuration.

Self-consistency is but one motive that shapes agency across the life course. In making sense of the array of motivated dynamics, it is useful to appeal to three overarching temperamental systems that energize motivated action: approach, avoidance, and effortful control (Carver and Connor-Smith, 2010; Caspi, 2000; Caspi et al., 1995). Studies of nonhuman animals, including octopi, goats, cats, marmots, and rhesus monkeys, support a two-factor conception of motivation that comprises exploratory (i.e., approach-oriented) behaviors on the one hand and protective (i.e., avoidance-oriented) behaviors on the other (Elliot and Covington, 2001; Mehta and Gosling, 2006). Procuring valuable resources and avoiding hazardous or risky situations are both vital survival tasks and hence are governed by two independent motivational systems. These motivational systems are orthogonal, which means that activity in one is generally unhelpful in predicting activity in the other and that outputs from both systems combine to produce distinctive patterns of action.

Applied to the life course, the approach system motivates a broadening of one's resources, seeking social support and moving toward positive, rewarding situations. It is indicated in adulthood by personality features such as optimism, extraversion and trait positive emotion (Andersson, 2012a; Hitlin and Elder, 2007). In contrast, the avoidance system motivates self-protection, social withdrawal and staying away from negative, undesired situations (Elliot, 2006; Elliot and Thrash, 2002). Personality indicators of this system include shyness, anxiety, neuroticism, and trait negative emotion (Carver and Connor-Smith, 2010; Caspi, 2000). Individuals vary meaningfully in their typical levels of approach and avoidance motivation; these fundamental temperamental variations are elaborated into personality structures across the life course and predict the successful navigation of key role transitions involving work, family and marriage (Caspi, 2000, 2002; Caspi et al., 1989), the weathering of relationship and work crises (Andersson, 2012b; Carver et al., 2010), and the acquisition of personal resources such as self-esteem and social network diversity (Andersson, 2012a; Caspi, 2000; Hitlin and Elder, 2007). Indeed, approach-oriented individuals seem more likely to accumulate multiple identities that then can serve as sources of resilience during difficult times (Thoits, 2003). Moreover, they should be more adept at handling conflict among role identities.

Meanwhile, effortful control is a superordinate temperament that involves the reflexive management and redirection of outputs from approach and avoidance motivation systems through top-down cognitive functioning (Carver and Connor-Smith, 2010). It is conceptually akin to executive self-control (Baumeister et al., 2007; Mischel et al., 1988). Deliberate, controlled action is important to the stability of occupational trajectories (Clausen, 1991) and to desistance from aggressive and violent behavioral tendencies (Sampson and Laub, 1993). Clausen's (1991) key disposition of planful competence includes elements of approach and effortful control; it is embodied by consistency, self-confidence, and intellectual vigor. Clausen describes the opposite of planful

competence as fearfulness, distrust, and a self-defeating outlook (1991: 836). In this way, it is similar to the inhibited temperament researched by Caspi and colleagues (Caspi, 2000; Caspi et al., 1989).

These three temperamental systems are biologically and genetically shaped. They are expressed from infancy onward, and are elaborated into complex personality systems across the life course through structural circumstances (McLeod and Lively, 2003) and cumulative and interactional continuity mechanisms (Caspi, 2000; Caspi et al., 1989). They exert effects on individual outcomes and life chances indirectly through personality formation and social selection processes and directly through deep emotional responses to particular life situations. Caspi (2000) describes continuity processes linking early temperament to adult personality structure. Adult personality factors of constraint, positive emotion, and negative emotion map onto temperamental variation in control, approach, and avoidance. In sum, Caspi conceptualizes adult personality as a 'social and cognitive elaboration' of temperamental styles (2000: 161).

As suggested by Caspi, the influence of agentic motivations on life course outcomes may reach its apex during periods of role transition. During transitory periods, new processes of role negotiation and learning come into play. Those who show a predominance of avoidance motivation often miss out on developmental opportunities by focusing too rigidly on potential threats and obstacles and reverting to ingrained habits that are unproductive in new role environments. At the same time, some level of avoidant functioning is invaluable to social adjustment, as it predicts refraining from certain delinquent behaviors and poor health behaviors (Hirsh et al., 2009). Indeed, some scholars have suggested that avoidant temperament, while counterproductive in excess, provides the very basis for 'socializability,' whereas approach temperament constitutes a key basis of motivated self-actualization and personal growth (DeYoung, 2006). Conceptual parallels can be found in Piaget's (1970) identification of key developmental tasks including assimilation into the social order and accommodation of shifts in knowledge, what Peterson (1999) interprets as core human tasks of both maintaining social order and adapting to change.

The diverse and wide-ranging impact of approach and avoidance motivation on life outcomes is showcased by its correlates in autobiographic life narratives. In a recent study, Wilt et al. (2011) examined relationships between personality and themes in life stories. They found that avoidant tendencies were linked to construals of threat whereas approach tendencies predicted themes of exploration. In previous research, McAdams (2006) had previously highlighted the importance of personality structure to understanding how individuals recruit and elaborate on basic American themes of contamination and redemption in developing life narratives.

In sum, the approach–avoidance theory of motivation is supported by investigations of animal and human behavior and lends uncanny purchase in understanding the structure and outcomes of motivation across the life course. Approach–avoidance temperament patterns, regulated by effortful control, evolve into complex personality systems and predict the success of key role transitions, engagement in adaptive and delinquent forms of behavior, and the development of various personal resources. Meanwhile, these basic temperaments mold the application of cultural knowledge to the interpretation of singular life events and to the construction of overarching life narratives.

New Directions

The move toward interdisciplinary research across the social sciences in the past decade serves to both validate life course studies' long-held core perspectives and suggests an exciting future for the study of human development in sociohistorical context. As suggested above, there is room for greater understanding of the nature of human motivation and choice as it intersects with structurally bounded changes, especially considering global economic shifts, the results of which are far from known. We suggest a few arenas of profitable life course research.

While there are more studies and data sets available that follow individuals throughout their lives, there is room for more linking of early life temperament and personality with later life motivations and choices. To what extent do early approach–avoidance tendencies exacerbate or mitigate social disadvantage? What factors lead to the development of perseverance in the face of obstacles, and do those forces operate differently across racial, ethnic, gender, and socioeconomic groups? Following up on Elder (2001) in a previous edition of the Encyclopedia, how can we best assess relative influences of individual and structural factors on agentic capacities as well as the employment of those capacities?

The principle of linked lives has rich possibilities for engagement with issues of motivation and agency. What sorts of significant relationships serve to 'push' individuals, or open up structurally blocked pathways? A good deal of research explores the role of marriage in terms of status attainment processes, less work deals with relationships such as mentoring (e.g., McDonald et al., 2007). Additionally, the typically domain-specific nature of much research has, to this point, precluded fruitful work that focuses on overlapping individual trajectories such as the work–family balance (Blair-Loy, 2003).

Many psychological models of motivation suggest a biological component in demonstrated capacities of perseverance as well as personality dispositions that influence situated interaction and life course trajectories. Future work should more fully link neurological, psychological, and sociological levels of analysis for understanding patterned variation and reciprocal influences across these levels of analysis.

Lifelong understandings are becoming more axiomatic in the study of human development, with developmental psychology, social psychology, and mainstream sociology journals regularly publishing longitudinal studies that focus on both individual and structural factors. Similarly, research-linking individual and social structural factors are becoming mainstream across the social sciences (McLeod and Lively, 2003), with advances in statistical modeling techniques enabling research to disentangle individual level processes from different levels of structural influence.

Abstract

Systems theory provides a powerful method for the description of homeostatic systems, that is, systems in which feedback-controlled regulation processes occur. Since human goal-directed behavior is regulated by such processes, systems theory is also very useful for psychological research. One of the most elaborated psychological models based on systems theory is the Zurich Model of Social Motivation by Bischof. This model postulates the existence of three basic motives or needs: the needs for security, arousal, and autonomy. Each of these is treated in a specific homeostatic subsystem, which is represented as a negative feedback loop. The model assumes that the attempt to maintain the appropriate amount of security, arousal, and autonomy for the respective need results in specific regulations of the distance to social partners. Furthermore, it is postulated that those three needs, and thus the way of distance regulation, take a specific developmental course. These assumptions are supported by several studies in which the distance regulation behavior of the participants was observed and simulated by means of a parameter estimation.

Systems theory provides a powerful method for the description of systems in which feedback controlled regulation processes occur. Since human goal-directed behavior is regulated by such processes, systems theory is also very useful for psychological research. One of the most elaborated psychological models based on systems theory, the Zurich Model of Social Motivation by Bischof (1985, 1993), will be presented below, together with some empirical evidence for its validity.

Systems Theory

Systems or control theory originated from practical, engineering-related questions concerning regulation processes. Its aim is to analyze the structure of systems and to provide adequate, preferably quantitative, models for them. The basic unit of systems control is a negative feedback loop which consists of the following elements: a detector which provides the system with information about the environment (input), a reference value which indicates what the input ideally should be, and an output function that causes the system in case of a discrepancy between input and reference value to 'behave' in a way that affects the environment in order to reduce the discrepancy (for details see Bischof, 1985, 1995).

The notion that processes such as these not only occur in machines, but also can be found in living systems such as animals or human beings was first introduced into the life sciences by Wiener (1948). Almost at the same time, it was also formulated in German by von Holst and Mittelstaedt (1971). Since then, this idea has appeared in different theories. The models based on systems theory, however, vary considerably in their degree of quantification, their complexity, and their generalizability.

One simple, general, and well-known example of a negative feedback loop used to characterize human behavior is the TOTE unit described by Miller et al. (1960). A more complex attempt to explain the general principles of goal directed behavior in terms of systems theory stems from Vohs and Baumeister (2011).

Since systems theory not only is especially apt for the description of purposive behavior, but also allows for the description of short-term as well as long-term regulation processes, models or theories dealing with more specific topics can be found in the fields of motivational as well as developmental psychology. Examples in the area of motivational psychology are the control theory model of work motivation by Klein (1989) and the control system model of organizational motivation by Lord and Hanges (1987). The former describes individual work motivation as a function of feedback and several cognitive processes. The latter also deals with task performance, but can be applied to individual motivation as well as interpersonal activities in organizations. A more comprehensive model, which is at least partly based on a systemic approach, is presented by Dörner (1994 1998), who intends nothing less than to discover the 'construction plan' of the human soul. In contrast to these authors, Hyland (1988) uses his motivational control theory as a meta-theoretical framework to integrate different, already existing, motivational theories which – according to him – reflect different aspects of a single underlying process which can again be described with a negative feedback loop.

In developmental psychology, a dynamic systems approach is used, for example, by Fogel and Thelen (1987) in their theory of motor development, even if they do not put it into terms of systems theory. The models of Burke (1991) and Bell (1971) are more explicitly based on systems theory. The former describes the process of identity formation as a negative feedback loop. The latter develops a control system to explain reciprocal socialization effects between children and their caregivers. A much broader model which is concerned with the general principles of human development is the developmental systems theory by Ford and Lerner (1992). The best known example for a systems approach in developmental psychology, however, is probably Bowlby's (1969) theory of infant attachment, a phenomenon which he viewed in feedback terms, although he never ventured to formulate it in a mathematical model. This was eventually performed by Bischof (1975,

1985, 1993), who provided a completely quantified model of social motivation. This is referred to as the Zurich Model of Social Motivation (or Zurich Model) and will be described in the following section.

The Zurich Model of Social Motivation

The Zurich Model of Social Motivation by Bischof (1985, 1993, Figure 1) arose from the want of a quantitative model able to explain and predict processes of social distance regulations. Such regulations have been described by attachment theorists such as Bowlby (1969) and also occur during individuation processes in puberty and adolescence. In short, the model postulates three basic motivational systems: the security, the arousal, and the autonomy system. All of these are represented as negative feedback loops and are considered homeostatic. In addition, there is a fourth system, the coping system, which deals with cases in which one of the other systems gets blocked and cannot operate in its usual manner. These four systems will

Figure 1 The Zurich Model of Social Motivation (after Bischof, 1993, p. 13).

be described qualitatively, although there also exists a mathematical description (Bischof, 1993; Gubler and Bischof, 1991; Gubler et al., 1994).

The Security System

Security is defined as the feeling of intimacy, warmth, protection, and so forth that one obtains when one is close to a familiar person, typically one's primary caregiver. This feeling has its source in three input variables, all of which are sensed by a specific detector. The detector for familiarity provides the information as to whether a certain object is familiar, in contrast to being new, unknown, or discrepant from one's expectancies. The detector for relevancy assesses the rank and the 'conspecificity' of the object in question. The detector's output is highest when the perceived object is an adult, high-ranking conspecific, and can be reduced, for example, by submissive behavior of the object or by substitution of a human adult by another object such as a child or an animal. The third detector gives information about the distance between oneself and the perceived object. The closer one is positioned to a familiar object the more security one obtains. Hence, the construct of security refers to a hypothetical emotional variable monotonically increasing with familiarity, relevancy, and proximity. Since proximity is the only one among those three variables which the subject can control, the obvious way to provide a homeostasis of security results in distance-regulating behavior.

The reference variable of the security system is the degree of dependency the subject feels. As long as dependency exceeds security, an appetence for security is maintained. This induces the subject to show attachment behavior, that is, to reduce the distance to a person who is able to provide security. The opposite situation, frequently encountered in puberty, results in an aversion against security and consequently in an avoidance of familiar persons (surfeit behavior).

The Arousal System

Arousal is defined as feelings such as interest, fascination, curiosity, as well as feelings of alarm or fear which can occur when one encounters a nonfamiliar person. Basically, the arousal system can be thought of as analogous to the security system, and moreover it can utilize the same three detectors. Like security, arousal is hypothesized to increase with the object's proximity and relevancy. Since the familiarity detector also provides information about how novel an object is, arousal can be connected to the output of this detector as well. Thus, the paradigmatic case for the arousal system is the encounter with a high-ranking, adult human stranger.

The reference value of the arousal system is labeled enterprise. Again, a distinction between an aversive and an appetent behavioral response can be made. Aversion against arousal and subsequent fear behavior result from arousal exceeding enterprise. If arousal falls short of enterprise, an appetence for arousal develops which leads to exploratory behavior.

The security and the arousal systems do not work independently of each other. Both systems respond to the same stimulus situations. Thus, the quantitative processing of the inputs involved leads automatically to effects such as fear-evoking stimuli intensifying attachment behavior towards an available caregiver, or the caregiver serving as a security base for exploratory ventures. Furthermore, the two systems do not develop independently during ontogeny. The reference variables – dependency and enterprise – are assumed to be negatively correlated, and to covary with the individual's age and maturity. Young infants are strongly dependent and only modestly enterprising. They need the presence of a security-providing caregiver in order to start exploring the environment and to acquire competence. Later in development, usually culminating around early adolescence, this pattern changes: growing independence and enterprise now demand and allow for the separation from the familiar partners and the establishment of new relationships. Finally, after adolescence, the two reference values normally level out.

The Autonomy System

The autonomy system can be regarded as analogous to the security and the arousal systems. The input here, however, stems from a different source. The detector which provides the amount of felt autonomy senses experiences of success such as obtaining obedience, acknowledgement, or admiration from other people, solving difficult problems, or being competent in certain subjects. Therefore, autonomy can be described as feeling competent, strong, and powerful, and having influence, prestige, and authority.

The reference variable of the autonomy system is called 'autonomy claim' and is closely related to the power and the achievement motives, as well as the need for prestige and an aspiration for self-confidence. In the case of a discrepancy between the feeling of autonomy and the autonomy claim, however, the model postulates the occurence of behaviors stemming clearly from the domain of power and dominance. If individuals feel an appetence for autonomy, they are assumed to behave assertively by becoming threatening, demanding, or even aggressive. In the opposite case, if individuals have too much autonomy and feel aversive, they will show submissive behaviors such as behaving humbly or servilely.

The autonomy claim is not independent of the other two reference variables, dependency and enterprise. On the contrary, the autonomy claim is postulated to underlie the connection of the security and the arousal system by affecting dependency negatively and enterprise positively.

The Coping System

The coping system operates in cases where one of the other systems gets blocked by an (internal or external) obstacle or barrier. The coping system provides three external and two internal coping strategies, external strategies being active attempts to change the situation and internal ones being efforts to adapt oneself to the situation. The three external coping strategies are labeled invention (searching for a detour), aggression (attempting to destroy the barrier), and supplication (begging someone else to remove the barrier). The two internal strategies are referred to as acclimatization (adaptation of the reference value to the input) and revision (adaptation of the perception of the situation).

Figure 2 Mean proximity to the security base (black points) and maximal proximity to the source of arousal (white points) in virtual distance units. Error bars indicate standard errors. Horizontal arrows show the nearest age groups which differ with $p \leq 0.05$.

The model does not predict which one of these coping responses is performed in a given context since this is primarily a result of the individual's learning history. However, it is assumed that the internal strategies will succeed if the external strategies do not lead to a success.

Empirical Evidence

The assumptions made by the Zurich Model of Social Motivation were tested by means of several behavior observations and estimation studies. Both types of studies were conducted with either very young children of about one year of age or with older participants ranging from late childhood to adulthood. Since the Zurich Model contains several ideas of attachment theory, settings similar to the Strange Situation Test by Ainsworth et al. (1978) were used for the younger children. For the older participants, a spaceship simulator was developed in which they experienced a space flight which was also designed according to the Strange Situation.

In this simulator, the participants were seated in a cockpit where the virtual space was visible on a computer screen. There were several instruments to manipulate in order to move, orient oneself in space, and protect the spaceship from dangers. The effects of the participant's actions were visible on the screen and the participants could hear sounds, such as their gun firing or the noise of the accelerating engine. In addition, the simulator was moved according to the steering maneuvers of each participant, which ensured a high emotional involvement.

During their virtual flights the participants were confronted with two different objects. One object was considered familiar (either the earth or a home base) and served as an orienting point in space as well as protection. The proximity of the participants to this security base served as a measure for their dependency. A novel object – a strange planet – also appeared during the flight. This planet was fascinating as well as potentially dangerous to the participants. The proximity to this source of arousal was used to assess the enterprise of the participants.

In the late 1980s and throughout the 1990s 14 studies were conducted with this spaceship simulator. Participants were for the most part schoolboys and girls as well as students between 9 and 33 years ($N = 704$, mean AGE = 21.2 years). The data obtained in these studies (Figure 2) strongly support one of the main theoretical assumptions made by the Zurich Model: dependency and enterprise correlate and take an inverse developmental course. The time of the biggest difference is attained at about 18 years, when dependency reaches its minimum while enterprise is at its maximum.

In the spaceship simulator, as well as the laboratory settings used for the younger children, the behavior of the participants was registered continuously. This allowed for investigation methods exceeding simple comparisons of groups by analyzing the distance regulation processes of single participants. In the

Figure 3 Example of simulated and real distance regulation behavior of one participant (after Gubler et al., 1994, p. 115). The vertical scale indicates virtual distance units, the horizontal scale represents the time of the flight.

estimation studies mentioned above, it was possible to simulate the actual behavior of the participants by means of a parameter estimation based on the mathematical formulation of the Zurich Model (Figure 3). These studies gave further evidence for the validity of the model (for details see Gubler and Bischof, 1991; Gubler et al., 1994).

Future Directions

While the functioning of the security and the arousal systems is sufficiently supported by empirical evidence, there are still several open questions for future research. Although the existing data also support the assumptions made about the autonomy system, the causal link of the autonomy claim to dependency and enterprise still has to be established. Since the Zurich Model was originally conceived from the point of view of a child, more adult motives such as altruism have to be included as well. Furthermore, the study of the developmental course taken by the different reference variables or motives also has to be extended to older age groups in order to get a model explaining the motivational development of the whole life span.

Motivational Development: Cross-Cultural Perspectives

Jan Hofer and Holger Busch, University of Trier, Trier, Germany

© 2015 Elsevier Ltd. All rights reserved.

Abstract

People differ in how well the consciously represented, explicit motives they pursue match their implicit motivational system. Such an alignment of explicit and implicit motives has beneficial effects on well-being. The article will first define implicit and explicit motives. Then, consequences resulting from an alignment of motivational systems are highlighted by reviewing research conducted with Euro-American samples as well as with a focus on cross-cultural research. We will demonstrate that implicit motives seem to universally impact the satisfaction derived from goal-pursuance. After summarizing findings on antecedents of motive congruence, an outlook on open questions in research is given.

> "I feel happy when something great was happening. When I am visiting interesting places while travelling or when I am remembering the journeys I've done in the past. I also feel happy when I am at home, when I feel fine, when everybody is well, when I am listening to the radio or when I spend time with my friends." (Elias, 9 years)

It might be odd beginning an article on implicit and explicit perspectives on motivational development across cultures with a boy's statement about happiness. Tackling the central question what makes people happy and flourish (Seligman and Csikszentmihalyi, 2000), we can deduce from his means to be happy that people's motives (e.g., striving for stimulation or close relationships) are crucial in this respect. Conclusive evidence exists that motives energize and direct individuals' behavior and thus shape developmental processes in the long run. If successful, development throughout various stages of life is often seen to be reflected in feelings of happiness and satisfaction (e.g., Erikson, 1959).

Unfortunately, not all motives are made equal. While some motives may be prominent components of the individual's true self (Waterman, 1993), other motivational sources of behavior are rather located outside the individual (Pepitone, 1976). Thus, realization of motives may not always lead to a sense of well-being. Based on the seminal paper by McClelland et al. (1989), we argue that implicit motives are a vital part of the individual's true self. Consequently, they represent a weighing disposition which determines the extent to which certain strivings and activities are considered emotionally pleasant and fulfilling. Above all, individuals able to attune their strivings with their implicit needs are supposed to benefit from success in goal-oriented behavior. We further argue that alignment of different types of motives represents a basic psychological process. Thus, even if culture-bound socialization goals and child rearing practices put varying emphasis on motivational domains, congruence between different motivational components of one's personality is likely to have positive effects on well-being across cultural contexts. In the following, we will first provide a definition of and distinction between implicit and explicit motives. We will then review the evidence for beneficial effects of congruence between implicit and explicit motives and summarize what is known about why individuals differ in how well their implicit and explicit motives are aligned. Finally, we will briefly sketch some open developmental questions in this area.

Dual-Motives Theory: Distinguishing between Implicit and Explicit Motives

In 1989, McClelland, Koestner, and Weinberger offered a compelling solution to a problem that had previously been controversially discussed in motivational psychology: Why were self-report measures of a given motive consistently found to be uncorrelated with thematic apperception measures of the same motive? While this finding had predominantly spawned a debate on the psychometric quality of thematic apperception motive assessment, McClelland and colleagues argued that the two approaches to motive measurement tapped into different motivational systems.

On the one hand, self-attributed or explicit motives (abbreviated *san* for self-attributed need) are those motivational end-states we consciously define as desirable. That is, explicit motives are the goals that we strive for, the plans we set for ourselves, and the values we cherish because we think there is some benefit in attaining them. As people are able to deliberately reflect upon whether they consider a given goal desirable, explicit motives are easily assessed via self-report instruments. The developmental reasoning is that explicit motives are learnt through verbal instructions by parents or other significant socialization agents. Thus, children need to have acquired a certain degree of language development as well as some basic self-concept that motivational concepts such as goals can be integrated into.

On the other hand, implicit motives (abbreviated *n* for need) are less cognitive but rather enduring affective preferences for the approach toward certain incentives and the avoidance of certain disincentives. That is, implicit motives have an impact on whether we seek out a given activity or situation because we expect to derive some pleasure from it (see Hofer and Busch, 2011; on adverse effects on well-being when motives are seen as frustrated). However, this motivational system eludes conscious reflection, although it is not necessarily inaccessible. People cannot report on their implicit motives. Thus, implicit motives need to be assessed through

thematic apperception techniques such as the Picture Story Exercise (PSE; McClelland et al., 1989) which asks participants to make up stories on picture cards depicting ambiguous social situations. Assuming these stories to be motive-toned interpretations of the given picture cues, they are content-coded and used to determine participants' motive strength. Here, the developmental argument is that implicit motives develop early in childhood and are primarily shaped through mechanisms of classical and operant conditioning (McClelland and Pilon, 1983). That is, implicit motives are not integrated into a conscious self-concept but energize and direct behavior on an affective level below conscious representation.

Thus, according to dual-motives theory, explicit and implicit motives represent independent motivational systems. Indeed, as noted before, explicit and implicit measures of the same motive are generally uncorrelated (note that this statistical independence cannot be accounted for by methodological differences between the two measurement approaches alone, cf Thrash, Elliot, & Schultheiss, 2007). There are, however, some individuals whose explicit and implicit motive strength matches well: For example, they score relatively high on both a thematic apperception measure of their implicit achievement motive and a self-report measure of their explicit achievement motive (for a discussion of potential differences between high–high and low–low motive-congruence patterns, see Langan-Fox and Canty, 2010). This phenomenon has been termed motive congruence. For others, there is a discrepancy between their explicit and implicit motive: For example, they might score low in their implicit achievement motive but high in their explicit achievement motive. Individual differences in motive congruence have been demonstrated to have an influence on well-being outcomes. Before we present corresponding evidence, however, we would like to briefly introduce the motives that are usually examined in this context and give a rationale as to why it is instructive to study motive congruence cross-culturally [cf 24 011: cross-cultural psychology].

Implicit motive research has focused on three motives: *n*Achievement, *n*Affiliation-Intimacy, and *n*Power. *n*Achievement is defined as a concern for efficacy and competence; *n*Affiliation-Intimacy is defined as the desire for contact and closeness to others; *n*Power is defined as the desire for having an impact on others' behavior and emotions (see Schultheiss and Brunstein, 2010; for an overview). *n*Affiliation-Intimacy combines two motivational tendencies for interpersonal closeness that are highly correlated but can still have different predictive validity (see Weinberger et al., 2010): Traditionally, *n*Affiliation denotes a concern for closeness for the sake of avoiding solitude, while *n*Intimacy denotes a concern for closeness for the sake of a mutually satisfying relationship.

It has been argued that these motives have evolved because they have increased evolutionary adaptation by increasing the chances of survival and/or reproduction (MacDonald, 1991). Consequently, they ought to be universal properties of human functioning. This does not necessarily mean, however, that all cultures provide the same developmental context for motive development. For example, on the level of explicit motives cultures differ widely in the values they endorse (Schwartz, 1992). Analogously, it seems reasonably safe to assume that cultural variations in parental ethnotheories and subsequent socialization in infancy (Keller, 2007) might lead to culturally diverse shaping of implicit motives. This refers not only to potential cultural differences in motive strength but also to potential differences in how a given motive is expressed. Indeed, there has been a debate about whether *n*Achievement comprises a social-oriented component in cultures stressing group belongingness over individual autonomy because in such cultures individual excellence might entail the disincentive of potential isolation (Maehr and Nicholls, 1980). Still, achievement-related behavior may irrespectively of cultural context be molded by other motives than *n*Achievement alone (see Sorrentino and Shepphard, 1978; for the relation between affiliative motivation and achievement behavior in US-Americans). Hence, we see cross-cultural research on implicit motives as a chance to arrive at insights into aspects of both universal human functioning and culture-specific variation in motivation.

Congruence of Implicit and Explicit Motives: Effects

A variety of studies has confirmed that individuals' well-being is increased when their implicit and explicit motives are in congruence. The general idea is that it is more beneficial in terms of well-being to pursue goals that are in line with affective preferences for certain incentives (i.e., implicit motives) than goals that are not. Pursuance of goals that are not rooted in one's implicit motivational system might also provide some pleasurable experiences (e.g., Hofer et al., 2011), for example through social confirmation. However, generally, scholars agree that it is more beneficial to pursue self-generated goals (e.g., Deci and Ryan, 2000). We argue that how authentically a goal has been self-generated is evidenced in its correspondence to the implicit motivational system.

We will review the evidence on effects of congruence of implicit and explicit motives separately for the three implicit motives in the following. Before we do so, we would like to point out that congruence effects have not only been found for the three single motives but that the broader motivational constructs of agency and communion (Bakan, 1966) have also been examined in this context. Brunstein, Schultheiss, and Grässmann (1998) combined *n*Achievement and *n*Power to form an agency motivation score and used *n*Affiliation-Intimacy as communion motivation score. What they found was that high commitment to motive-congruent goals predicted increases in emotional well-being over four months, while high commitment to motive-incongruent goals was associated with a decrease in well-being. Using the same combinations as Brunstein et al. (1998), Pueschel, Schulte, and Michalak (in press) found that only motive congruent goal progress was associated with less depressive symptoms in their sample of outpatients.

Measuring needs for communion in the context of romantic partnerships on an implicit and an explicit level, Hagemeyer, Neberich, Asendorpf, and Neyer (in press) showed that motive-congruent individuals were more satisfied with their relationship and ran a significantly lower risk of relationship breakup over a one-year period.

With respect to *n*Achievement, Baumann et al. (2005) found that motive congruence was associated subjective well-being. Interestingly, they also found that in a sample of patients diagnosed with heterogeneous psychosomatic and psychiatric disorders achievement motive congruence predicted reduced emotional and somatic complaints. Thus, according to Baumann et al., motive incongruence can be interpreted as a hidden stressor which people are not aware of but still can aggravate psychological symptoms. Similarly, Kehr (2004) hypothesizes and finds in a longitudinal study that motive incongruence – aggregated across all three motives – decreases volitional resources. In support of this notion, Job et al. (2010) demonstrated that motive incongruent individuals have an inclination toward unhealthy eating behavior such as snacking which can be interpreted as a stress-reducing strategy.

The first study to investigate motive congruence effects in a non-WEIRD sample (the acronym WEIRD has been introduced by Henrich et al., 2010; to denote Western, educated, industrialized, rich, and democratic societies which are massively overrepresented in present mainstream psychological literature) was provided by Hofer and Chasiotis (2003). Zambian male adolescents reported on their life-goals and had their implicit motives assessed. Like in all other studies conducted in a non-WEIRD cultural context reported in the following, all instruments were tested on whether they were unbiased in the given cultural sample (see Hofer et al. (2005); for procedural details on testing if a motive-measure is culturally unbiased [cf 23 148: methods of cross-cultural research in developmental psychology]). For *n*Achievement, the expected beneficial effect of motive congruence was identified in that a combination of a high implicit and a high explicit achievement motive was associated with higher levels of life satisfaction.

With respect to *n*Affiliation-Intimacy, two studies on motive congruence have already been referred to: Both Brunstein et al. (1998) and Pueschel et al. (in press) found motive congruence for *n*Affiliation-Intimacy to be beneficial for various measures of well-being, albeit the term communion was used in said studies. Recently, following Weinberger et al.'s (2010) suggestion to analyze *n*Affiliation and *n*Intimacy as two related but yet distinct motives, Busch and Hofer (in preparation a) demonstrated that motive congruence for *n*Intimacy but not for *n*Affiliation was predictive of people's self-reported willingness to settle disagreements with their romantic partner in a cooperative manner.

Particularly interesting from a developmental point of view are results yielded by Hofer et al. (2006): They studied how motive congruence for *n*Affiliation-Intimacy related to interpersonal identity development [cf 23 193: identity formation during adolescence and cultural variations]. According to Marcia's identity status model (e.g., 1966), there are two dimensions characterizing of identity formation: Exploration denotes an active search for identity elements such as beliefs, attitudes, and role perceptions, while commitment denotes the individual's investment in an identity element. Identity diffusion means that there is neither exploration nor commitment; moratorium means that there is exploration but no commitment has yet been made; identity foreclosure means that without any exploration, commitment is made to identity elements that were adopted from parents; finally, identity achievement means that commitment has been made after exploration has taken place. What Hofer, Busch, and colleagues (2006) found was that motive congruent individuals were more likely to have an achieved identity and less likely to have a foreclosed identity in the interpersonal domain (e.g., ideas about friendship, dating). That is, those individuals who set their affiliative goals in line with their implicit affiliation-intimacy motive relied less on others to tell them who they were but found their own answer to this question. Thus, motive congruence is not only linked to positive well-being but also to the outcome of important developmental tasks.

Hofer and Chasiotis (2003) replicated the beneficial motive congruence pattern in their sample of Zambian male adolescents. As was the case with *n*Achievement, a combination of high *n*Affiliation-Intimacy and pronounced importance of intimacy goals was associated with high levels of life satisfaction. Also, in Cameroonian, Costa Rican, and German adults the same beneficial motive congruence effect on general life satisfaction was identified (Hofer et al., 2006): However, explicit motives were not represented by goals but values. In a hierarchy of explicit motives, values are more abstract than goals, thus play a more passive role in influencing actual behavior than goals, and rather denote what a person feels he/she ought to do rather than what he/she wants to do (Emmons, 1989; Kluckhohn, 1951). More specifically, benevolence values were assessed as the concern for others' welfare as a guiding principle in life (Schwartz, 1992). Thus, Hofer et al. (2006) not only demonstrated that motive congruence has positive effects on well-being in very different cultural contexts but also that these effects (at least for *n*Affiliation-Intimacy) hold across various degrees of abstractness of explicit motive formulation.

With respect to *n*Power, only a single study has demonstrated that motive congruence in this domain is associated with increased well-being. Of course, power was included in the agency scores employed by Brunstein et al. (1998) and Pueschel et al. (in press). Power itself, however, was examined only by Hofer et al. (2006) who found that congruence between *n*Power and power values was not related to well-being in their Cameroonian, Costa Rican, and German samples. Following up on this finding, Hofer et al. (2010) could further specify conditions for motive congruence in the power domain to be associated with well-being: In their German and Hong Kong as well as mainland Chinese samples, power values again did not interact with *n*Power to predict well-being. On the other hand, power goals did. As acceptance of institutionalized power is a defining characteristic of cultures (Hofstede, 2001), power values might be too abstract and too devoid of behavioral implications (cf Emmons, 1989) to identify the actual potential of motive congruence effects in this motivational domain. An interesting finding in its own right of Hofer, Busch, Bond, Li, and Law's (2010) study was that power values were positive in terms of individuals' well-being if they were translated into power goals. This suggests that power values might rather be deficiency-oriented, that is, attractive to those who have little

opportunity to experience power, while power goals might rather be approach-oriented.

To conclude, research has consistently found that motive congruence positively affects well-being. That is, such effects have been found for all three basic motives and across various cultural contexts, suggesting that implicit motives may universally be considered as a type of weighing disposition determining whether the pursuance of a particular goal is experienced as satisfying and pleasurable (see Schultheiss et al., 2008). Moreover, motive congruence has been linked to actual behavior (Job et al., 2010) and developmental milestones (Hofer et al., 2006). Thus, motive-congruence seems to be an important factor in individuals' positive development.

Determinants of Congruence of Implicit and Explicit Motives

With motive congruence effects established, researchers have also directed their attention toward the question of why some people pursue motive congruent goals while others pursue rather motive incongruent goals. Experimental studies have shown that imagining the outcomes (e.g., motive-specific positive affect) of motive-directed behavior makes people commit more strongly to motive congruent goals (Job and Brandstätter, 2009; Schultheiss and Brunstein, 1999). That is, people get more willing to pursue goals that allow them to actually experience the emotional states of motive satisfaction they have previously imagined. A second line of research has identified personality characteristics that make some people more likely to set motive congruent goals: Among the traits that were associated with motive congruence were self-determination (Thrash and Elliot, 2002), state orientation (Baumann et al., 2005), private body consciousness, self-monitoring, preference for consistency (Thrash et al., 2007), and referential competence (Schultheiss et al., 2011). These personality characteristics have in common that they denote a person's capacity to gain accurate introspective insight and based on this insight come to conclusions concerning their behavior, including goal setting.

The only study to investigate this issue cross-culturally was conducted by Hofer et al. (2010). Following Thrash and Elliot's (2002) reasoning, they hypothesized self-determination, defined as the ability to get in touch with one's inner needs and direct one's behavior accordingly, to be predictive of achievement motive congruence in Cameroonian, German, and Hong Kong Chinese adults. Results confirmed this assumption, suggesting that introspection universally is a resource of motive congruence. Thus, there is some evidence as to which factors affect motive congruence. More research, however, is urgently needed to get a clearer picture of how individual differences in motive congruence can be accounted for.

Motive Congruence Research: Future Directions and a Developmental Outlook

As reviewed above, motive congruence has consistently proven to be predictive of enhanced well-being and decreased psychological symptoms. Interestingly, it has also been linked to the resolution of a central developmental crisis: motive congruent adolescents were more likely to have an achieved and less likely to have a foreclosed identity status (Hofer et al., 2006). Based on this finding, one might ask if motive congruence has beneficial consequences for personality development in general.

Second, we have reviewed the findings on how individual differences in motive congruence can be accounted for. These findings are meaningful in that they show, with an experimental as well as with a correlational design, that gaining insight into one's implicit motive system allows one to set congruent goals. They do not provide an answer as to how motive congruence develops in the first place. To answer this question, a proper base of knowledge is needed on the development of implicit motives. These two questions, i.e., how motive congruence might foster positive development and how implicit motives develop, will be outlined in some more detail in the following.

Motive Congruence in Positive Development

Implicit motives are known to influence long-term behavioral trends (McClelland, 1987) such as vocational choices (Jenkins, 1994). Moreover, implicit motives have been demonstrated to predict developmental outcomes such as generativity (Hofer et al., 2008; McAdams, 1985). That is, implicit motives may predispose some individuals to successfully resolve certain developmental crises more easily than others. Based on developmental demands, individuals may find themselves confronted with the task of highlighting specific goals, for example generative ones. Given a corresponding implicit motive constellation (high *n*Intimacy as well as high *n*Power; see McAdams, 1985), some people might find these goals more attractive and easier to internalize to begin with. While this is in itself an interesting idea that has received only little attention in psychological research, even less research has been devoted to testing if motive congruence might have an even stronger beneficial effect on positive development. The findings presented by Hofer, Busch, and colleagues (2006) suggest just this for the developmental task of identity formation.

Future research might want to test this assumption for other developmental tasks located at different points across the lifespan. For example, young adults in what Erikson called the intimacy crisis aiming at establishing a long-term, mutually satisfying relationship with a romantic partner might benefit if their intimacy goals are backed up by a corresponding implicit intimacy motive. Also, individuals' life-review might be more positive in old age if people have pursued motive congruent goals in their lives as these can be regarded as reflecting a person's true self (cf Waterman, 1993). In sum, the role of motive congruence in positive development has not been appropriately recognized, let alone complex interactions such as how developmental demands might increase motive congruence. This might be particularly relevant for identity formation in which long-term goals and motivational self-images have to be installed: Implicit motives may be the criterion against which goals and other identity elements are affectively

evaluated and goal commitment may be more likely for those goals that are in line with one's implicit motives.

Development of Implicit Motives

Unfortunately, only little is known about how implicit motives develop. The most influential study has been presented by McClelland and Pilon (1983): They assessed implicit motives in then-adult children of mothers who had been interviewed on child-rearing behavior when their children had been 5 years of age. Relating mothers' description of their child-rearing behavior during the first 5 years of their children's childhood and children's implicit motive scores more than 20 years later, McClelland and Pilon found that *n*Achievement was predicted by the severity of toilet training and *n*Power by mothers' permissiveness for children's sexual and aggressive behavior. Examining *n*Affiliation and *n*Intimacy separately, McClelland and Pilon found the latter to be correlated with the extent of praise by their mothers, while the former was related to mothers' unresponsiveness to their child's crying. These longitudinal data provide information on how maternal parenting shapes implicit motives. However, they rely on mothers' retrospective account of their child-rearing behavior.

In general, beyond these findings, empirically sound knowledge on implicit motive development is scarce. Only few studies have examined implicit motives in children and sought for antecedents of motive strength. Moreover, the studies there often have serious methodological problems such as using picture cues for implicit motive assessment that were originally developed for adults and have not been tested for suitability for children or not using a practice run of the implicit motive assessment for children to get acquainted with the task (e.g., Kagan and Moss, 1959). Recently, a research program has started to assess implicit motives in children with age-adequate picture cues and instructions that present the task in a playful manner. The program has yielded first encouraging results (Busch and Hofer, in preparation b) in that parental child-rearing practices could be identified as predictive of children's motive strength that were comparable to those presented by McClelland and Pilon (1983): For example, *n*Power was highest when parents facilitate both impulsive as well as social behavior in their children.

Thus, PSE or related instruments (e.g., employing preschool versions of the Implicit Association Test which in its adult version has already been used for the assessment of implicit motives; see, e.g., Brunstein and Schmitt, 2004; Cvencek et al., 2011; respectively) for measuring children's implicit motives are currently being developed. With these instruments available much more fine-grained analyses of implicit motive development will be possible which will hopefully lead to a clearer picture of how individual differences in motive strength can be accounted for by childhood experiences.

This established, cross-cultural research provides the opportunity to identify universally valid as well as culture-specific antecedents of implicit motive development. As Greenfield et al. (2003) have argued, across different cultures various developmental pathways can lead to the same developmental outcome. For implicit motive development this could mean that some parenting characteristics might be identified which foster the development of a given motive in various cultural contexts. Still, the way that individuals act out their motivational impulses might be culturally different. For example, as described previously, people in WEIRD societies with their focus on individualism might be more inclined to realize their achievement motive by striving for sticking out as the best. In cultures with a stronger focus on group-belonging, this motive realization might be less well regarded because it entails social isolation. To date, few studies have taken a cross-cultural perspective on which factors might facilitate or impede the realization of implicit motives. For example, on the basis of findings presented by Winter et al. (1998) that behavioral and experiential correlates of implicit motives are moderated by personality traits, Hofer and Busch (in preparation) found personality traits to channel implicit motive realization across cultural groups. While these results indicate cross-cultural similarities, what is nevertheless needed is an open mind for potential cultural variations in how implicit motives are expressed.

To wrap things up, implicit motives have proven to act as weighing dispositions if goal pursuit is perceived as emotionally satisfying. That is, the 9-year-old we quoted at the beginning of the present article might perceive the activities he mentions as making him happy because they match his implicit motive system. Research has shown that motive congruent goal pursuit is associated with enhanced well-being. What is more, this effect has been demonstrated in various cultural contexts. Furthermore, there is first evidence that the resolution of developmental crises can also benefit from motive congruence. This line of research needs to be further elaborated upon, however. Second, research on the development of implicit motives is still in its infancy. Better knowledge on how implicit motives develop is an indispensable basis for understanding in more detail why some people tend to commit to motive incongruent goals and suffer from impaired affective rewards of goal pursuit.

Motor Control Models: Learning and Performance

Pietro G Morasso, Italian Institute of Technology, Genoa, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The focus of the article is on the variety of attempts that have been investigated for capturing the complexity of purposive action and adaptive behavior, having defined a coordinated action as a class of movements plus a goal. Redundancy is a side effect of this connection, and thus redundancy is necessarily task oriented, something to be managed 'online' and rapidly updated as the action unfolds. The article then analyzes two main computational mechanisms that have been proposed as candidates of how the brain may deal with motor redundancy: (1) the force-field-based solution known as Equilibrium-Point Hypothesis (EPH) and (2) the cost-function-based solution to the degrees of freedom problem, namely Optimal Control Theory. However, both theories apply only to overt actions where force fields and cost functions are directly related to the interaction of the body with the physical world in the course of a real action. Considering that overt actions are just the tip of the iceberg, hiding the vast domain of covert actions that are the skeleton of motor cognition, an extension of EPH is described, Passive Motion Paradigm (PMP). The relationships between PMP, the simulation theory of covert actions, internal models, and the body schema concept are also analyzed. Finally, general learning mechanisms that may support the acquisition of internal computational modules are briefly summarized.

Modeling the way in which humans learn to coordinate their movements in daily life or in more demanding activities is an important scientific topic from many points of view, such as the medical, psychological, kinesiological, and cybernetical. The article analyzes the complexity of this problem and reviews the variety of experimental and theoretical techniques that have been developed for this purpose.

With the advent of technical means for capturing motion sequences and the pioneering work of Marey (1894) and Muybridge (1957) in this area, the attempt at describing, modeling, and understanding the organization of movement has become a scientific topic. The fact that human movements are part of everyday life paradoxically hides their intrinsic complexity and justifies initial expectations that complete knowledge could be achieved simply by improving the measurement techniques and carrying out a few carefully designed experiments. Unfortunately, this is not the case. Each experiment is frequently the source of more questions than answers, and thus the attempt to capture the complexity of purposive action and adaptive behavior, after a century of extensive multidisciplinary research, is far from over.

The conventional view is based on a separation of perception, movement, and cognition and the segregation of perceptual, motor, and cognitive processes in different parts of the brain, according to some kind of hierarchical organization. This view is rooted in the empirical findings of neurologists of the nineteenth century, such as J. Hughlings Jackson, and has a surprising degree of analogy with the basic structure of a modern PC that typically consists of input and output peripherals connected to a central processor. Perhaps the analogy with modern technology justifies why this old-fashioned attitude still has its supporters, in spite of the massive empirical and conceptual challenge to this view and its inability to explain the range of skills and adaptive behaviors that characterize biological organisms.

Let us consider perception, which is the process whereby sensory stimulation is translated into organized experience. That experience, or percept, is the joint product of the stimulation and of the process itself, particularly in the perception and representation of space. An early theory of space perception put forth by the Anglican bishop G. Berkeley at the beginning of the eighteenth century was that the third dimension (depth) cannot be directly perceived in a visual way, because the retinal image of any object is two-dimensional, as in a painting. He held that the ability to have visual experiences of depth is not inborn but can only result from logical deduction based on empirical learning through the use of other senses.

The first part of the reasoning (the need of a symbolic deductive system for compensating the fallacy of the senses) is clearly wrong, and the roots of such misconception can be traced back to the neoplatonic ideas of the Italian Renaissance in general, and to Alberti's window metaphor in particular. Also, the Cartesian dualism between body and mind is just another face of the same attitude and such *Descartes' error*, to quote Damasio (1994), is on a par with the *Berkeley's error* described in the preceding paragraph, and is at the basis of the intellectualistic effort to explain the computational complexity of perception that characterizes a great part of the classic artificial intelligence approach. However, the latter part of Berkeley's conjecture (the emphasis on learning and intersensory integration) is surprisingly modern and agrees, on one hand, with the modern approach to neuropsychological development pioneered by Piaget (1963), and on another hand, with the so-called *connectionist* point of view, originated in the 1980s as a computational alternative to classic artificial intelligence.

An emergent idea is also the motor theory of perception, well illustrated by Berthoz (1997); that is, the concept that perception is not a passive mechanism for receiving and interpreting sensory data but is the active process of anticipating the sensory consequences of an action and thereby binding the sensory and motor patterns in a coherent framework. In computational terms, this implies the existence in the brain of some kind of 'internal model,' as a bridge

between action and perception. As a matter of fact, the idea that the instructions generated by the brain for controlling a movement are utilized by the brain for interpreting the sensory consequences of the movement is already present in the pioneering work of Helmholtz and von Uexküll, and its influence has resurfaced in the context of recent control models based on learning (e.g., Wolpert and Kawato, 1998). The generally used term is 'corollary discharge' (von Holst and Mittelstaedt, 1950), and implies an internal comparison between an outgoing signal (the *efferent copy*) and the corresponding sensory *re-afference*: the coherence of the two representations is the basis for the stability of our sensorimotor world. This kind of circularity and complementarity between sensory and motor patterns is obviously incompatible with the conventional reasoning based on hierarchical structures. A similar kind of circularity is also implicit in Piaget's concept of 'circular reaction,' which is assumed to characterize the process of sensorimotor learning; that is, the construction of the internal maps between perceptually identified targets and the corresponding sequence of motor commands.

An additional type of circularity in the organism/environment interaction can be identified at the mechanical interface between the body and the outside world, where the mechanical properties of muscles interact with the physics of inanimate objects and gravity. This topic area has evolved from the Russian school, with the early work on the nature of reflexes by I.P. Pavlov and the subsequent critical reexamination by Anokhin (1974) and Bernstein (1967). In particular, we owe to Bernstein the seminal observation (the *comparator model*) that motor commands alone are insufficient to determine movement but only identify some factors in a complex equation where the world dynamics has a major influence. This led, among other things, to the identification of muscle stiffness as a relevant motor parameter and the formulation of the theory of equilibrium-point control (Feldman and Levin, 1995; Bizzi et al., 1992).

In general, we may say that, in different ways, Helmholtz's corollary discharge, Piaget's circular reaction, and Bernstein's comparator model are different ways to express the *ecological nature* of motor control; that is, the *partnership* between brain processes (including muscles) and world dynamics. On top of this, another type of circularity from a more cognitive point of view is suggested by the parietofrontal *mirror circuit* (Rizzolatti and Sinigaglia, 2010), which is proposed as the unique mechanism "that allows an individual to understand the action of others *from the inside* and gives the observer a first-person grasp of the motor goals and intentions of other individuals."

On the other hand, these general ideas on motor control could not provide, immediately, mathematical tools of analysis from which to build models and perform simulations. The art and science of building motor control models is a later development and has been influenced by the methods designed by engineers in the field of automatic control and computer science. Most of the techniques are based on linear approximations and explicit schematizations of the phenomena. In particular, two main concepts can be singled out for their influence on the study of motor control: the concept of *feedback* and the concept of *motor program*, both of them originating from the seminal work on cybernetics initiated by Norbert Wiener (1948). Their level of influence in brain theory is certainly determined by the tremendous success of these techniques in the modern technological world. However, their direct applicability to what we may call the *biological hardware* is questionable for three main reasons: (1) feedback control can only be effective and stable if the feedback delays are negligible, but this is not the case for biological feedback signals, where transduction and transmission delays add up to tens of milliseconds; (2) the concept of motor program implies a sequential organization, which only can be effective if the individual steps in the sequence are sufficiently fast, and this is in contrast with the parallel, distributed processing of the brain made necessary by the relative slowness of synaptic processing; and (3) the degrees of freedom (DoF) problem, further analyzed in the following section, implies that engineering modeling techniques, typically conceived for low-dimensional applications, cannot be scaled up easily due to the so-called curse of dimensionality.

Motor Redundancy and the 'Cybernetics of Purposive Actions'

Since the time of Nicholas Bernstein (1967) it has become clear that one of the central issues in the neural control of movements is the 'degrees of freedom problem,' that is, the computational process by which the brain coordinates the action of a high-dimensional set of motor variables for carrying out the tasks of everyday life, usually described and learned in a 'task-space' of much lower dimensionality. Such dimensionality imbalance is usually named 'motor redundancy.' This means that the same movement goal can be achieved by an infinite number of combinations of the control variables and timing patterns, which are equivalent as far as the task is concerned. But in spite of so much freedom, experimental evidence suggests that the brain consistently uses a narrow set of solutions. Consider, for example, the task of reaching a point B in space, starting from a point A, in a given time T. In principle, the task could be carried out in an infinite number of ways, with regards to spatial aspects (hand path), timing aspects (speed profile of the hand), and recruitment patterns of the available DoFs (kinematic DoF). In contrast, it was found that the spatiotemporal structure of this class of movements is strongly stereotypical, whatever their amplitude, direction, and duration: the path is nearly straight (in the extrinsic, Cartesian space, not the intrinsic, articulatory space), and the speed profile is nearly bell shaped, with symmetric acceleration and deceleration phases (Morasso, 1981). That this stereotypicity should be attributed to internal control mechanisms, not to biomechanical effects, is suggested by the analysis of reaching movements in different types of neuromotor impaired subjects and the adaptation of normal subjects to disturbing force fields (Shadmehr and Mussa-Ivaldi, 1994).

A movement, per se, is nothing unless it is associated with a goal and this usually requires recruitment of a number of joints, in the context of an action. Recognizing the crucial importance of multijoint coordination was really a paradigm shift from the classical Sherringtonian viewpoint (typically

focused on single-joint movements), to the Bernsteinian quest for principles of coordination or synergy formation. A coordinated action is a class of movements plus a goal. Redundancy is a side effect of this connection and thus redundancy is necessarily task oriented, something to be managed 'online' and rapidly updated as the action unfolds.

Generally speaking, actions can be considered as operational modules in which descending motor patterns are produced together with the expectation of the (multimodal) sensory consequences. Mounting evidence accumulated in the last decades from different directions and points of view, such as the equilibrium point hypothesis, mirror neurons system, and motor imagery, suggest that in order to understand the neural control of movement, the observation and analysis of overt movements is just the tip of the iceberg, because what really matters is the large computational basis shared by action production, action observation, action reasoning, and action learning.

How the Brain May Deal with Motor Redundancy

Let us consider again the stereotypicity of reaching movements that emerges in a robust way from the redundancy of the human motor system: where is it coming from? Two main alternatives, although with many variants, have been investigated in the last decades: one is based on force fields and nonlinear attractor dynamics and the other on cost functions and optimal control concepts.

The Force-Field-Based Solution to the DoF Problem: The Equilibrium-Point Hypothesis

The best-known example of a force-field-based solution to the DoF problem is the Equilibrium Point Hypothesis (EPH) (Asatryan and Feldman, 1965; Feldman, 1966; Bizzi et al., 1976, 1992; Feldman and Levin, 1995). The force field comes from the elastic properties of muscles and their capacity to store and release mechanical energy.

The elastic properties of muscles are well captured by the so-called λ-model (Feldman and Levin, 1995). In this model, λ is the controllable parameter that sets the activation threshold of the monosynaptic stretch reflex and thus determines the 'rest length' of the 'muscle spring.' Its value is specified by supraspinal motor commands and expresses a combination of the desired levels of muscle length and stiffness. By setting the λ-commands of all the muscles, the brain implicitly codes an equilibrium point, determined by the fact that at this point the spring actions cancel each other. In this way, movement follows as a mechanical consequence of the force field, without a continuous intervention of the brain, and the brain can take advantage of a second type of redundancy (in addition to the 'kinematic redundancy,' determined by the excess number of DoFs), namely 'muscle redundancy,' determined by the excess number of muscles in relation to the number of DoFs.

A crucial feature is that muscles are not linear springs but are characterized by length–tension curves of exponential type, whose stiffness depends on the difference between the λ-command and the actual muscle length. Therefore, the brain has the opportunity of independently controlling two variables: (1) the global equilibrium point, by setting the λ-commands equal to the muscle lengths of a desired posture (the reciprocal component of the λ-commands); and (2) the global stiffness of the joints, by adding to the previous pattern a set of coactivation λ-commands in such a way that the stronger the coactivation, the stronger the stiffness.

Beyond the specific neuromuscular details of the λ-model, EPH is important because it assigns a computational role to the muscles, in addition to its obvious executive action. Summing up, the power of the EPH comes from its ability to solve the DoF problem by positing that the redundant posture of the whole body is not directly controlled by the brain in a detailed way but is the biomechanical consequence of the equilibrium among a large set of muscular and environment forces. In this view, movement is a symmetry-breaking phenomenon, that is, the transition from an equilibrium state to another.

The Cost-Function-Based Solution to the DoF Problem: Optimal Control Theory

Optimal control theory is a classical engineering design technique for controlling complex systems in which infinite solutions are possible, given a desired task or behavior. The general idea is that in order to design the best possible controller of a system, capable to carry out a prescribed task, one should define first a 'cost function,' that is, a mathematical combination of the control variables that yields a single number (the 'cost' of the action). This function is generally composed of two parts: a part that measures the 'distance' of the system from the goal of the action and a part (regularization or penalty term) that encodes the required 'effort.' The design is then reduced to the computation of the control variables that minimize the cost function, thus finding the best possible trade-off between accuracy and effort.

The first attempt to apply this approach to human motor control was carried out by Flash and Hogan (1985), by proposing the 'integrated jerk' as the regularization term of the cost function. 'Jerk' is the time derivative of acceleration, and thus minimizing jerk is equivalent to maximize the smoothness of the generated trajectory. They showed that the solution of such minimization tasks for point-to-point, planar reaching movements was indeed consistent with the spatiotemporal invariances found by Morasso (1981). However, other simulation studies found similar results by choosing different types of cost functions, such as 'integrated torque change' (Uno et al., 1989) or 'motor noise dependent statistics' (Harris and Wolpert, 1998). Thus, it is not clear how to identify the cost function, supposedly used by the brain, because different alternatives tend to yield similar behaviors.

In this line of research, optimal control concepts were used for deriving offline optimal control patterns, to be employed in feed-forward control schemes. A later development (Todorov and Jordan, 2002) suggested using an extension of optimal control theory that incorporates sensory feedback in the computational architecture. In this closed-loop control technique, a block named 'control policy' generates a stream of motor commands that optimize the predefined cost function on the basis of a current estimate of the 'state variables'; this

estimate integrates in an optimal way (by means of a Kalman filter) feedback information (coming from delayed and noise-corrupted sensory signals) with a prediction of the state provided by a forward model of the system's dynamics, driven by an 'efference copy' of the motor commands. One of the most attractive features of this formulation, in addition to its elegance and apparent simplicity, is that it blurs the difference between feed-forward and feedback control because the control policy governs both. On the other hand, the mathematical computations that need to be carried out in order to identify the optimal control policy are quite complex and do not scale up well with dimensionality. Moreover, optimal feedback control requires indeed feedback, and thus is unable to treat overt and covert actions in a uniform way.

Beyond EPH: The Passive Motion Paradigm as a General Approach to Action Generation

In the EPH framework, the computational core of the mechanism is based on force fields and the associated attractor dynamics rather than on cost functions. In the standard formulation, the source of the force fields is physical and is determined by the mechanical properties of muscles. Therefore, this model can only be applied to overt, not covert, movements. However, it is possible to abstract the model to the attractor dynamics of interacting neural representations, and this is proposed by the Passive Motion Paradigm (PMP) (Mussa-Ivaldi et al., 1988). The basic idea can be formulated in qualitative terms by suggesting that the process by which the brain can determine the distribution of work across a redundant set of joints, when the chosen end-effector is assigned the task of reaching a target point in space, can be represented as an internal simulation process that calculates how much each joint would move if an externally induced force (i.e., the goal) pulls the end-effector by a small amount toward the target. This internal simulation in turn causes the incremental elastic reconfiguration of the internal *body schema* involved in generating the action, by disseminating the force field across the kinematic chain (more generally, task-specific kinematic graph) that characterizes the articulated structure of the human or robotic body. The mechanism is labeled 'passive' in line with the EPH. The underlying hypothesis is that the equilibrium point is not explicitly specified by the brain, which just contributes to the activation of 'task-related' force fields. The mechanism is robust and can be easily extended to high-dimensional problems because there is no need to solve ill-posed inverse problems but only to run an internal simulation of the dynamic body schema. This mechanism applies equally well to covert and overt actions, and this is consistent with the mounting evidence from brain-imaging studies in support of common neural substrates being activated during both 'real and imagined' movements. For this reason, it is plausible to posit that also real, overt actions are the results of an internal simulation, where such simulation is a result of the interactions between an 'internal body model' with the attractor dynamics of force fields induced by the goal and task-specific constraints involved during the performance of any action. If the mental simulation converges (i.e., the goal is realized), then the movement can be executed. Otherwise, convergence failure may play the role of a crucial internal event, namely the starting point to break the action plan into a sequence of subactions, by recruiting additional DoFs, employing tools that may allow the realization of the goal, and so forth. In this sense, PMP can be considered a generalization of EPH from action execution (overt actions) to action planning and reasoning about actions (covert actions).

The dynamics of PMP networks is driven by a kind of internal potential energy, associated with the previously described attractor dynamics. The basic idea is not far away from the 'free-energy principle' advocated by Friston (2010) in order to account for action, perception, and learning in a unified way; and it is, at the same time, an alternative to the optimal control theory (Mohan and Morasso, 2011).

Examples of PMP Networks

Let $\vec{q}$ be the set of all the DoFs that characterize the human body or the body of a humanoid robot, possibly extended by including the DoFs of a tool. Any given task identifies one or more end-effectors, and is defined by the motion of one end-effector with respect to another or to some reference point. The natural reference frame for $x(t)$ is linked to the environment (extrinsic) space and not the joint (intrinsic) space. Moreover, the dimensionality of $\vec{q}$ is generally much greater than the dimensionality of $\vec{x}$.

The basic idea of the PMP is to express the goal of an action (e.g., 'reach a target point $\vec{x}_T$') by means of an attractive force field $\vec{F}_{tgt} = K\,(\vec{x}_T - \vec{x})$, centered in the target position and apply it to the body schema, in particular to the task-related end-effector. This force field is mapped into a set of torques applied to the joints according to the Jacobian matrix of the arm: $\vec{T}_{tgt} = J^T K\,(\vec{x}_T - \vec{x})$. The displacement of the articulations is then determined by an admittance matrix A that distributes the motion among the (redundant) set of joints: $d\vec{q} = A\,J^T K\,(\vec{x}_T - \vec{x})$. By integrating over time, this equation and mapping articulations displacements into small displacements of the end-effector ($d\vec{x} = J\,d\vec{q}$), the whole body schema will evolve from the initial equilibrium configuration to a final, desired configuration where the force applied to the end-effector is null because the end-effector has reached the target. This dynamics of the body schema can also be expressed by means of a graph (or kinematic network) such as that in the top panel of Figure 1. The graph also includes a nonlinear gain that allows to reach stability in a prescribed time, according to the theory of *terminal attractors* (Zak, 1988). The relaxation process, from the initial equilibrium state to the final one, is analogous to the mechanism of coordinating the motion of a wooden marionette by means of strings attached to the terminal parts of the body: the distribution of the motion among the joints is the 'passive' consequence of the virtual forces applied to the end-effectors and the virtual compliance of the joints. The extension from a single limb to the whole body of humans or humanoid robots is quite straightforward, as shown in the bottom panel of Figure 1.

This modeling framework can be successfully applied for explaining the formation of Whole Body Reaching (WBR) synergies, that is, coordinated movement of lower and upper limbs, characterized by a focal component (the hand must

Figure 1 **Top panel**. Basic kinematic network that implements the passive motion paradigm for a simple kinematic chain. It includes the Gamma function, which endows the system with terminal attractor dynamics. This means that equilibrium is not achieved asymptotically but in finite time. (The corresponding speed profile is also shown.) External and internal constraints (represented as task-dependent force/torque fields) bias the path to equilibrium in order to take into account suitable 'penalty functions.' This is a multi-referential system of action representation and synergy formation, which integrates a forward and an inverse internal model. **Middle panel**. The figure illustrates the key element of the architecture of Figure 1 for solving the degrees of freedom problem, namely the mapping of the force field, defined in the extrinsic space and applied to the end-effector, into the corresponding torque field, defined in the intrinsic space and applied to the joints. The mapping is implemented by means of the transpose Jacobian matrix of the kinematic transformation. Dimensionality reduction is obtained implicitly by letting the internal model 'slide' in the torque field. Each point of the trajectory in the extrinsic space corresponds to a whole manifold in the intrinsic space (the 'null space' of the kinematic transformation). The equilibrium point in the force field corresponds to an equilibrium manifold in the torque field. The selection among the infinite number of possible targets is carried out implicitly by the combination of different force/torque fields. **Bottom panel**. Full kinematic network of the iCub robot (53 DoFs; see Sandini, G., et al., 2004). Each blue box corresponds to a basic kinematic network (top panel) for a specific body segment. 'Tools' corresponds to possible interaction points between the external world and the internal body mode; the corresponding green arrows identify potential goals and the related goal-oriented force fields. Such force fields are propagated through the global network (blue arrows), searching for a task-dependent equilibrium configuration. A single or multiple time-base generators control the timing. Sandini, G., Metta, G., Vernon, D., 2004. RobotCub: an open framework for research in embodied cognition. In: Proceed. 4th IEEE/RAS Intl Conf. on Humanoid Robots, LA, CA, 13–32.

reach a target) and a postural component (the center of mass (CoM) must remain inside the support base) (Morasso et al., 2010). The focal component of the task was modeled by means of a simple attractive field to the target, applied to the fingertips of both hands. The postural component was implemented by an additional force field applied to the pelvis region. By simulating the network in various conditions it was possible to show that it exhibits many of the spatiotemporal features found in experimental data of WBR in humans (Stapley et al., 1999; Pozzo et al., 2002; Kaminski, 2007), in particular the fact that the speed profiles of the hand and the CoM are synchronized (Figure 2).

Figure 3 shows the PMP network used for the bimanual coordination of the movements of a humanoid robot. The network, in this case, is composed of three parts, one related to the left arm, a second related to the right arm, and a third to the trunk. Task-specific networks are logically derived from the global whole-body network (the global body schema) by 'grounding' some element of the network, that is, inhibiting the propagation of the task-related force fields beyond a given articulation or body part. In this sense, the body schema represented by PMP networks is not a passive map but is a dynamic structure that recruits at run-time the redundant DoF of the body in the context of task-related force fields.

PMP and the Simulation Theory of Covert Actions

Experimental results (in terms of EEG, fMRI, PET, and NIRS) generally support the idea of common underlying functional networks subserving both the execution and imagination of movements (Kranczioch et al., 2009; Munzert et al. 2009). Marc Jeannerod (2001) went a step forward by formulating the Mental Simulation Theory (2001), which posits that cognitive motor processes such as motor imagery, movement observation, action planning, and verbalization share the same representations with motor execution. The neural activation patterns include not only premotor and motor areas such as the PMC (premotor cortex), SMA (supplementary motor area), and M1 (primary motor cortex) but also subcortical areas of the cerebellum and the basal ganglia. In particular, the presence of activity in the typically motor regions suggests that covert actions are in the same motor format that is required by overt actions. The concurrent activation of descending motor pathways might be involved in the generation of efference copies that propagate upstream

Figure 2 Coordination of whole-body reaching movements by means of the passive motion paradigm. For the same target, the top panel shows two motion patterns obtained with different values of the admittance matrix A, namely the hip admittance is reduced from 2.5 rad s^{-1} Nm (left graph) to 0.1 rad s^{-1} Nm (right graph). The bottom panel shows the time course of the joint rotations, including the time base generator $\Gamma(t)$, (left graph) and the speed profiles of the end-effector and the center of mass.

to parietal and premotor cortices, thus predicting the potential consequences of the planned action. Jeannerod interprets this brain activity as an 'internal simulation' of a detailed representation of action and uses the term *S-states* for the corresponding mental states. The crucial point, in our view, is that if S-states occurring during covert actions are to a great extent quite similar to the states occurring during overt actions, then it is not unreasonable to posit that also real, overt actions are the results of an internal 'simulation' process. This is the basic idea behind the PMP. From this point of view, the simulation of PMP networks is a way to generate what Jeannerod calls 'S-states.'

A closely related issue is that of understanding actions of conspecifics and learning by imitation. One of the explanations proposed is that observation of other's actions would activate, in the observer's brain, the same mechanisms that would be activated, were that action imagined by the observer himself or herself (Gallese and Goldman, 1998). Imitation, as suggested by Iacoboni, could be based on directly matching the observed action onto an internal simulation of that action (Iacoboni, 2009). Internal simulations hence play an important role in allowing the observer to foresee the consequence of an action, predict the intended goal of the actor, and learn to replicate the action through imitation. In a recent study, Mohan et al. (2011) demonstrated how humanoid robots can learn a range of motor skills by observing a teacher, with PMP framework as a central building block. They further demonstrated how abstract motor knowledge acquired by the humanoid robot iCub while learning one skill (drawing) can be reused while learning another, quite different skill (controlling a 2 DoF toy-crane), hence drastically speeding up learning. These results further support the idea of PMP being a unified computational framework for execution, reasoning, understanding, and imitation of action, thus suggesting a strong link between PMP, EPH, simulation theory of covert actions, and mirror neurons systems. In sum, PMP networks can be activated under a variety of conditions in relation to action, either of oneself or observed from other individuals. Their function is not only to shape the motor output during action execution, but also to provide the self with information on the feasibility, consequence, understanding, and meaning of potential actions. What remains out of this article is the set of processes that allow 'action schemas,' generated by a PMP mechanism, to interact with neuromuscular and external world dynamics.

Figure 3 Bimanual coordination task (reaching two objects at the same time) for the iCub robot implemented by means of the passive motion paradigm. **Panel (a)**: kinematic network, with two target goals and a single time-base generator. The network includes three modules: (1) right arm, (2) left arm, and (3) waist. The dimensionality of $\mathbf{J_R}$ & $\mathbf{J_L}$ is 3×10 (this includes the seven DoF's of the arms and the three DoF's of the waist). The dimensionality of $\mathbf{A_j}$ is 7×7 and of $\mathbf{A_T}$ is 3×3. The three subnetworks interact through a pair of nodes ('assignment' and 'sum') that allow the spread of the goal-related activation patterns. This simplified network is obtained from the global network of **Figure 2** by 'grounding' the waist, that is, by inhibiting the spread of activation to the lower limbs. **Panels (b and c)** show the initial and the final postures of the robot and the two cylindrical target objects. **Panels (d and e)** show the trajectories of the two end-effectors and the corresponding speed profiles (together with the output $\Gamma(t)$ of the time base generator). **Panel (f)** clarifies the intrinsic degrees of freedom in the left-arm-torso chain. **Panel (g)** shows the time course of the waist and left-arm joint rotation patterns: J0–J2: joint angles of the waist (yaw, roll, pitch); J3–J9: joint angles of the right arm (shoulder pitch/yaw/roll; elbow flexion/extension; wrist pronation/supination/pitch/yaw).

Learning Paradigms in Neural Networks and Motor Control

At the core of the theories of neural network models is the attempt to capture general approaches for learning from experience tasks that are too complex to be expressed by means of explicit or symbolic models (Arbib, 1995). The mechanism of learning and memory has been an intriguing question after the establishment of the neuron theory at the turn of the nineteenth century (Ramón y Cajal, 1928) and the ensuing conjectures that memories are encoded at synaptic sites (Hebb, 1949) as a consequence of a process of learning. In accordance with this prediction, synaptic plasticity was first discovered in the hippocampus, and nowadays it is generally thought that LPT (long-term potentiation) is the basis of cognitive learning and memory, although the specific mechanisms are still a matter of investigation.

Three main paradigms for training the parameters or *synaptic weights* of neural network models have been identified: (1) 'Supervised learning,' in which a teacher or a supervisor provides a detailed description of the desired response for any given stimulus and exploits the mismatch between the computed and the desired response or error signal for modifying the synaptic weights according to an iterative procedure. The mathematical technique typically used in this type of learning is known as *back propagation* and is based on a gradient-descent mechanism that attempts to minimize the average output error (Rumelhart et al., 1986); (2) 'Reinforcement learning,' which also assumes the presence of a 'supervisor' or a teacher but its intervention is only supposed to reward (or punish) the degree of success of a given control pattern, without any detailed input–output instruction (Sutton and Barto, 1998). The underlying mathematical formulation is aimed at the maximization of the accumulated reward during the learning period; (3) 'Unsupervised learning,' in which there is no teacher or explicit instruction and the network is only supposed to capture the statistical structure of the input stimuli in order to build a consistent but concise internal representation of the input. The typical learning strategy is called Hebbian, in recognition of the pioneering work of D.O. Hebb, and is based on a competitive or self-organizing mechanism that uses the local correlation in the activity of adjacent neurons and aims at the maximization of the mutual information between stimuli and internal patterns.

How to link the learning paradigms above, which have been derived for explaining the plasticity of specific neural networks, to learning paradigms that apply to complex 'naturalistic' behaviors and thus involve a number of networks as well as the dynamics of the outside world, is still an open question that will require significant experimental and theoretical improvements in the coming years.

Abstract

The motor cortex evolved in mammals to supplement an ancestral motor system. It provides three advantages in the control of movements: more accurately graded forces, the generation of novel motor synergies, and the separation of existing motor synergies into individually controlled components. Plasticity in motor cortex neurons underlies learned skills and contributes to recovery of function after brain damage or disease. Recently, neural signals from the motor cortex have been used to control mechanical devices or to directly excite muscles, thus bypassing damaged parts of the motor system and restoring a measure of independence to patients with motor disabilities.

Definition

The motor cortex has been defined in two ways. According to the narrow definition, the motor cortex corresponds to Brodmann's area 4, an area that contains a motor representation of the entire body and sends outputs that control voluntary movements. In this sense, the motor cortex corresponds to the primary motor cortex, often abbreviated as M1 or MI. According to the broad definition, the motor cortex encompasses the primary motor cortex as well as a set of additional motor areas collectively called the premotor cortex or the non-primary motor cortex. This article applies the narrow definition. Article Premotor Cortex on the premotor cortex deals with the motor cortex in the broad sense. Defined in either way, the motor cortex is a part of the cerebral cortex and of the neocortex (*see* Cerebral Cortex). In primates, these areas compose the caudal (posterior) part of the frontal lobe, and in other mammals they are usually located in the rostral (anterior) part of the cerebral cortex (Figure 1).

Identifying Features of the Primary Motor Cortex

Like other parts of the cerebral cortex, the primary motor cortex has a laminated structure. It differs from most of the cerebral cortex, however, in that it lacks a clearly identifiable layer 4, also known as the internal granular layer. For this reason, the primary motor cortex is classed among the agranular areas of neocortex, along with several premotor areas and some caudal parts of the prefrontal cortex. In many primates, the primary motor cortex differs from other areas in that it is significantly thicker than other cortical areas.

In addition to its agranular architecture, three features distinguish the primary motor cortex from other parts of the neocortex. Electrical stimulation of the primary motor cortex evokes movements more easily than it does from other cortical areas. This trait is often measured by passing small amounts of electrical current through an electrode that has been inserted directly into the cortex, an experimental procedure known as intracortical microstimulation. Although some other areas come close, the electrical currents needed to evoke a movement consistently are usually smaller in the primary motor cortex than in other areas. The second defining feature involves thalamic connectivity. The primary motor cortex receives relatively direct inputs, via neural relays in the dorsal thalamus, from both the basal ganglia and the cerebellum. The third defining feature depends on topology, the spatial relationships among structures. The primary motor cortex lies immediately rostral to the somatosensory cortex.

In some primate species, the primary motor cortex has an additional defining feature. The neurons that project to the spinal cord have their cell bodies in layer 5. Some of these neurons reach a conspicuously large size and rank among the largest neurons in the cerebral cortex. Called Betz cells, these giant pyramidal cells can reach 60 μm in width in some monkeys and up to 120 μm in humans.

Figure 1 A rat brain, a rhesus monkey brain, and a human brain showing the approximate locations of the primary motor cortex (M1) in gray.

Connections of the Primary Motor Cortex

Cells in the primary motor cortex send outputs to and receive inputs from somatosensory cortex, the posterior parietal cortex, and the premotor cortex. Each of these regions consists of several areas, and nearly all of these projections are reciprocal. In addition to other cortical areas, some cells in the primary motor cortex project to the basal ganglia (specifically, to the striatum), to the cerebellum (via the basilar pontine nuclei), to the red nucleus, to the reticulospinal neurons of the brainstem, and to the spinal cord, among other structures.

At least parts of each of these structures play a role in controlling movements.

The older literature contains discussions of an *extrapyramidal motor system*, one largely dependent on the basal ganglia, as contrasted with a *pyramidal motor system* that emanates from the primary motor cortex. This term refers, not to the pyramidal cells that give rise to the corticospinal projections, but rather to the fiber tract that these and other axons form in the brainstem: the pyramidal tract. The idea of an extrapyramidal motor system has been discarded for several reasons. First, some basal ganglia function is mediated via its connections with the primary motor cortex, including pyramidal-tract outputs from the motor cortex. Second, a key part of the so-called extrapyramidal motor system, the supplementary motor area, was classed as such because it was once said to lack pyramidal-tract and corticospinal projections. Later research, however, showed that this nonprimary motor area has direct projections to the spinal cord that are nearly as extensive as those of the primary motor cortex. In fact, the primary motor cortex only contributes ~40% of the axons that compose the pyramidal tract, with axons from the premotor, somatosensory, and posterior parietal areas contributing the remainder. Third, basal ganglia function extends beyond the control of movements.

History of Motor Cortex Studies

Compared to other parts of the motor system, the primary motor cortex has a short evolutionary history, as the next section explains. As a subject of research, however, it has a very long history. About 2500 years ago, physicians of the Hippocratic school noticed that damage to the cerebral cortex on one side of the brain caused paralysis on the opposite side of the body. By the nineteenth century, the brain damage causing this motor impairment had been localized to a restricted part of the frontal lobe. Independently, G. Theodor Fritsch and Eduard Hitzig in Germany and David Ferrier in England came to believe that the caudal-most part of the frontal lobe controlled voluntary movement, and they set out to confirm this hypothesis experimentally. They used the then-novel phenomenon of electricity to evoke movements by stimulating the cerebral cortex. Unlike the method of intracortical microstimulation, mentioned above, these early researchers used much stronger currents, which they applied to the surface of the brain. The experiments of Fritsch, Hitzig, and Ferrier demonstrated that signals emanating from the motor cortex in dogs and monkeys produced movements on the opposite side of the body. This point is taken up again in the section on the motor map.

At the time, this research raised controversies that have reawakened in recent decades. Antivivisectionists, the forerunners of today's animal rights advocates, condemned the research of Fritsch, Hitzig, and Ferrier and argued then, as their successors do today, that research on dogs and monkeys does not apply to humans. These critics were wrong then, as they are today. The early neuroscience of Fritsch, Hitzig, and Ferrier established the existence of the motor cortex in a way that proved to have as much validity for humans as it did for other mammals. Although the primary motor cortex has become modified during evolution, no one now doubts that the primary motor cortex in dogs, humans, and monkeys, along with many other mammals, such as rats (Figure 1), derives from an ancestral species common to all of them.

Evolution of Motor Cortex

The primary motor cortex evolved in mammals, as did the other parts of the neocortex. As a result, only mammals have a primary motor cortex in the sense used here. Because the motor cortex evolved long after many of the other neural structures that control movement – such as the cerebellum, the red nucleus, parts of the basal ganglia, the reticulospinal system, and the spinal cord – it probably evolved to improve the performance of the remainder of the motor system. After the primary motor cortex developed, the motor system as a whole changed and some of the subcortical motor-control structures became less important.

The exact emergence of the primary motor cortex during mammalian evolution remains less certain than for the primary sensory areas, such as the primary (striate) visual cortex, primary auditory cortex, and primary somatosensory cortex (Kaas, 2011). The reason is that, unlike these and some other sensory areas, it has proven difficult to establish whether there is a separate primary motor cortex in certain groups of mammals. These mammals, specifically marsupials and monotremes, descend from species that diverged from placental mammals relatively early in mammalian history. For many sensory areas of neocortex, it has been possible to identify homologues in monotremes and marsupials, as well as in a broad diversity of placental mammals. For the primary motor cortex, however, no corresponding area has been convincingly identified in monotremes or marsupials, and there is evidence that the primary somatosensory cortex of marsupials has some of the properties that, in other mammals, characterize the primary motor cortex. As a result of these findings, it seems most likely that a separate primary motor cortex first emerged in early placental mammals, although some of its functions might have been performed by the primary somatosensory cortex in marsupial and monotreme mammals.

Although all placental mammals have a primary motor cortex, this area has adapted and changed in each species. For example, in New World monkeys with prehensile tails, much of the primary motor cortex controls tail movements. Likewise, in many primate species, including humans, much of it became specialized for hand use.

In particular, anthropoid primates (monkeys, apes, and humans) evolved a reliance on somatosensory (haptic) processing. As in all placental mammals, the primary motor cortex of anthropoid primates sends a massive corticospinal projection. In most mammals, however, the axons of the corticospinal neurons do not terminate directly on motor neurons or they do so only sparsely. By tracing axonal connections across multiple synapses in rhesus monkeys, it has been possible to show that the rostral part of the anthropoid primary motor cortex shares this characteristic with other mammals (Rathelot and Strick, 2006). Its corticospinal projections terminate mainly on spinal interneurons, not on motor neurons. That is, they lack monosynaptic connections with motor neurons. In contrast to the rostral part of the primary motor cortex, its caudal part projects monosynaptically to spinal motor

neurons, at least in anthropoid primates. This part of the primary motor cortex receives inputs predominantly from sensory receptors in the skin (cutaneous inputs) that have high sensitivity. The appearance of two divisions of the primary motor cortex probably occurred in anthropoid primates, and the existence of these two areas has been confirmed in studies of the human brain. The caudal part, the one dominated by cutaneous inputs, lies in the banks of the central sulcus in most anthropoids and has been called the caudal primary motor cortex in monkeys (abbreviated M1c) or posterior area 4 in humans (abbreviated area 4p).

The importance of this anthropoid specialization appears to relate to hand use. Cutaneous inputs probably play a role in the manipulation of objects by providing feedback concerning skin deformation for movements so fine that they do not change joint angles or muscle lengths very much, if at all. (The section on the function of motor cortex takes up the function of proprioceptive inputs, which signal muscle length.) This anthropoid specialization for haptic exploration likely evolved to provide advantages in fruit selection. The compliance of fruits to manual deformation often provides the most useful and sometimes the only, information about ripeness. In support of this idea, a comparison of nine species of anthropoids showed that the density of Meissner corpuscles correlates with the extent of each species' fruit consumption (Hoffmann et al., 2004). Meissner corpuscles are sensitive cutaneous receptors that respond to small amounts of skin stretching and deformation. The relationship between the density of Meissner corpuscles and a frugivorous diet probably reflects a variable ability to use hardness cues to assess the ripeness of fruits. Low-force finger movements also provide information about the texture of objects. By analogy with the visual system, this specialization of the hand – and especially of the fingers and finger tips – has been called a tactile 'fovea.' Sustained electrical stimulation of the primary motor cortex evokes coordinated movements resembling the manipulation of objects (Graziano, 2005).

Motor cortex function is intimately related to that of the parietal cortex, which has also changed dramatically during evolution. Specifically, the posterior parietal cortex is very small in most nonprimate mammals, including the close relatives of primates such as tree shrews. Thus most of its subdivisions likely evolved in early primates, in which they project to the primary motor cortex and to the premotor cortex. Sustained electrical stimulation of the posterior parietal cortex evokes coordinated reaching, defensive, and grasping movements, much as it does from the motor cortex. Each part of the posterior parietal cortex receives a different set of visual and somatosensory inputs and each projects to primary motor and premotor areas from which stimulation evokes similar movements (Kaas et al., 2011). Accordingly, these paired parietal and frontal regions probably act as functional modules for particular coordinated actions.

The Motor Map

For the primary motor cortex, the existence of a systematic topographic representation of the body has been recognized since the nineteenth century (*see* Topographic Maps). By observing the progression of epileptic seizures, the British neurologist J. Hughlings Jackson discerned the topographic organization of the primary motor cortex. In the motor cortex, it takes the form of somatotopy, a map of the body. From medial to lateral along the primary motor cortex, cells control the leg and foot, the arm and hand, and the face, mouth, tongue, and lips, in an ordered sequence.

The finer organization of the motor cortex is more complex and more difficult to summarize than the well-ordered topography of the somatosensory, visual, and auditory systems. As a general statement, the fingers, toes, and other distal parts of the body are more prominently represented in the caudal part of the primary motor cortex, whereas proximal representations are more prevalent rostrally. There are many exceptions to this tendency, however.

There has been some controversy over the extent of ipsilateral motor control from the primary motor cortex. For primates, it has long been known that the primary motor cortex sends a significant proportion of its corticospinal projection to the ipsilateral spinal cord. Until recently, however, it was not known whether these projections directly synapse upon spinal motor neurons. Recent research has confirmed that nearly all of the relatively direct influences of the primary motor cortex go to muscles on the side of the body opposite to each hemisphere. Stimulation of the primary motor cortex does not reveal any monosynaptic inputs to motor neurons on the ipsilateral side of the spinal cord. Using a technique called spike-triggered averaging, it is possible to show that the discharge of an individual cell in the primary motor cortex of monkeys correlates with a transient increase in muscle activity. This occurs, however, only for muscles contralateral to the hemisphere in which the cell is located. And although some neural discharges seem to correlate with movements of the ipsilateral limb, a careful analysis has shown that this activity can be attributed to small muscle contractions in the contralateral limb (Soteropoulos et al., 2011).

The Function of Motor Cortex

Despite more than a century of research, the function of the primary motor cortex is still not well understood. The earliest understanding came from studying the effects of brain lesions. A number of severe motor disabilities follow such lesions, including weakness, the loss of fine motor control, and in some circumstances complete paralysis. According to one widely held view, the primary motor cortex permits the fractionation of movement. This phrase refers to the independent control of muscle groups that usually work in concert with each other, as synergistic muscles. According to this idea, the fractionation of movement adds flexibility to the motor system by dissociating the components of motor synergies. A related idea is that the motor cortex underlies the construction of novel motor synergies. Discussions of this idea usually involve finger movements, but the primary motor cortex has a representation of the entire body, so its functions must apply more generally. The fine control of face, lip, and tongue movements also reflects flexible synergies, for example. The primary motor cortex does not, however, have any appreciable role in the control of eye movements.

Muscles versus Movements

A longstanding issue regarding the primary motor cortex is known as the muscles versus movement debate. This topic engaged researchers for many years, and it became controversial because it encompassed several separate issues. The question is: does the motor cortex control muscles or movements?

Edward Evarts developed a method to answer one aspect of this question. In the early 1960s, he recorded the activity of individual neurons in the primary motor cortex of monkeys as they made simple limb movements or generated forces against a mechanical device without moving. He found that motor cortex cells had much the same activity in either case. This answered the question from one perspective: the primary motor cortex generates forces, and these forces sometimes (but not always) cause the changes in joint angles that lead to movements. Evarts's findings have been repeatedly confirmed, both in experiments involving forces against variable loads and forces generated against an immovable object. In this sense, the motor cortex controls muscles (forces), not movements per se.

But there are other aspects of the same question, and in this sense it remains an open one. Hiroshi Asanuma suggested that each cell in the motor cortex controlled a single muscle. He used intracortical microstimulation to show that as the current decreases, the stimulation eventually causes the twitch of only one muscle. With more sophisticated methods, however, Paul Cheney and Eberhard Fetz showed that individual cells control the activity of many muscles, often those that act synergistically. They found, using spike-triggered averaging, that the activity of single cells in the primary motor cortex caused increases in muscle activity for several, synergistic muscles at more-or-less the same time. So, in this sense, the motor cortex controls coordinated movements, not (individual) muscles.

Yet another aspect of the question concerns the coordinate frame in which movements are controlled. Some cells in the primary motor cortex reflect a limited amount of information about how these movements occur in visual space, but for the most part the transformation from visual coordinates to motor commands occurs in posterior parietal and premotor areas. This aspect of the debate remains active. Although there is little doubt that the primary motor cortex controls muscles (forces), it may also have a role in controlling movements (joint-angle changes).

Population Coding

Apostolos Georgopoulos and his colleagues showed that neurons in the primary motor cortex encode the direction of hand movements. Each motor cortex cell has its greatest activity for movement in one direction, with systematically less activity as the direction of movement diverges from that *preferred direction*. On the assumption that these cells generate movements in their preferred direction, it is possible to estimate a collective directional signal emanating from a neuronal population. This computation, termed the *population vector*, matches the trajectory of movements very well. The same applies to forces without movement, although most research has involved actual movements of the hand.

Many different kinds of population codes have been shown to have the same basic properties as the population vector, and sometimes it is not necessary to record the activity of isolated neurons to detect something about intended movement direction. Although activity at the single-cell level provides the most information about the trajectory of movements, less refined neural signals also encode this information. In recent years, for example, it has been possible to decode movement direction from the clustered activity of dozens or hundreds of cells and from small electrical potentials, called local field potentials (LFPs), that reflect the activity of thousands of neurons and synapses.

Voluntary and Reflex Movement

The primary motor cortex has long been known to control voluntary movements, but it also plays a role in reflexive movements, called transcortical reflexes. For example, cells in the primary motor cortex integrate sensory information about coordinated shoulder and elbow movements. These signals can counter imposed forces within 50 ms, and exciting the motor cortex with transcranial magnetic stimulation potentiates this reflex response (Pruszynski et al., 2011).

Recent evidence shows that the flow of cutaneous information to the motor cortex is strongly regulated by the brain. All movements cause sensory signals from peripheral receptors, such as the Meissner corpuscles mentioned earlier. Gating mechanisms regulate the flow of this information to the motor cortex. During preparation for a movement, the primary motor cortex, but not the somatosensory cortex or the spinal cord, shows suppression of cutaneous inputs. Furthermore, the greater such suppression, the faster that monkeys can generate the planned movement (Seki and Fetz, 2012). Thus motor planning facilitates movements, in part by suppressing cutaneous inputs.

Motor Learning

During motor learning, such as mastering a sequence of movements or learning to overcome imposed forces in order to reach directly to a target, regional blood flow rates change in several motor areas, including the primary motor cortex. Article Cortical Areas Engaged in Movement: Neuroimaging Methods on the cortical areas engaged in movement, as revealed by neuroimaging methods, discusses these findings.

Single-cell studies in monkeys have revealed changes in the primary motor cortex that mirror the rate of motor learning and its decay. When monkeys experience forces that perturb their arm during reaching movements, several trials of practice enable them to overcome these forces. The number of such perturbations is important, but so too is their frequency (number of perturbations per unit time). The more frequently the monkeys experience the perturbation, the faster they can learn making straight movements to their target. With faster learning, however, comes faster decay of those memories and a reversion of the original prelearning state. Some neurons in primary motor cortex change their activity in a way that reflects the total number of experienced perturbations and not their frequency. Unlike the monkey's behavior, these plastic changes decay at the same rate for faster and slower learning. Other cells, however, depend on both the number and frequency of

perturbations, with faster neuronal changes occurring when learning is faster and a faster decay occurring thereafter, as observed at the behavioral level (Mandelblat-Cerf et al., 2011). These findings support the idea that plastic changes in the primary motor cortex underlie motor learning.

Neural Plasticity and Rehabilitation

In the United States, nearly 1% of the population has suffered a stroke that caused a motor disability. Recovery of function usually proceeds slowly and often remains incomplete. Research has shown that because of brain plasticity, organizational changes occur in the remaining primary motor cortex and in nearby areas that promote the recovery of function (Barbay et al., 2006). This plasticity reflects changes in the balance between cortical inhibition and excitation, which in turn changes the motor maps and level of activation.

A month of heightened plasticity seems to follow lesions of the primary motor cortex. From research on nonhuman animals, it appears that intense rehabilitative training within the first five days or so of brain damage may cause yet additional damage. Waiting for more than a month, however, seems to decrease both the plasticity and the recovery of function. In brain-damaged humans, rehabilitation efforts often come later and with less intensity than indicated by experiments on nonhuman animals. Future improvements in rehabilitation management might therefore involve increases in the intensity and frequency of treatments in a period from one to four weeks after the injury (Krakauer et al., 2012).

Neural Prosthetics

Neural prosthetics promise to assist motor control and communication in patients with damage to the motor cortex or its output pathways to muscles. These devices are intended to restore a measure of independence to these patients, who retain the ability to plan and imagine movements.

The most common approach is to deliver motor commands from the brain to some apparatus, often mediated by a computer. Such brain–machine or brain–computer interfaces can involve an apparatus as simple as a switch or a cursor on a video display, or one as complex as a robotic arm or an artificial limb. Some methods involve recording signals external to the brain, but many have involved the insertion of electrodes directly into the primary motor cortex. The neural commands used to operate these devices similarly range from electroencephalograpic and magnetoencephalographic signals to LFPs and cell recordings.

So far, the clinical applications have been limited, but two paralyzed patients have gained some control over their environment by using motor cortex activity to control various prosthetic devices, including a robotic arm (Hochberg et al., 2012). Another patient has regained some communicative skills (Kennedy et al., 2011).

In addition to mechanical devices and video displays, neural signals can be used to stimulate muscles directly. For example, monkeys have learned to use artificial connections from motor cortex cells to muscles in order to generate movements (Moritz et al., 2008; Ethier et al., 2012). In one of these studies, monkeys simultaneously controlled several neuron–muscle pairs to make hand movements. Likewise, a human quadriplegic has learned to use cortical recordings to command a simulated arm with muscles modeled in a realistic way (Chadwick et al., 2011).

Several challenges remain for developing clinically useful devices. It remains to be demonstrated which of the several competing approaches to the design and implementation of neural prosthetics will prove to be the most beneficial to patients. Furthermore, recording and decoding the intentions of patients depends on stable recordings over a long period. Perhaps most importantly, existing neural prostheses usually use vision, alone, to guide movement, and lack the somatosensory feedback of normal movements. Much of the early work in this field involved the control of cursors or levers along a single dimension. Obviously, a higher level of control is desirable. Like the patients mentioned above, monkeys have been trained to use motor cortex activity to control a simulated arm that has three dimensions of movement, as well as to control a gripper at the end of the arm for feeding movements (Velliste et al., 2008).

Sociological Implications

Research on the motor cortex has at least two sociological implications. First, like the antivivisectionists mentioned in the section on the history of motor cortex studies, contemporary animal rights advocates claim that research on monkeys and other nonhuman animals has no relevance to humans. Contrary to their opinions, the development of devices that enable paralyzed and mute people some control and independence has depended crucially on monkey research. Without monkey research motivated by the muscles versus movement debate and a desire to understand the structure, function, and evolutionary history of the primary motor cortex, there would be no neural prosthetics.

Second, both neural prostheses and improved rehabilitation methods promise to have important effects on society. More than one-third of stroke patients live for over a decade after sustaining brain damage, as do patients with brainstem and spinal injuries. Their contribution to society is much less than it could be. The ability to restore to them a measure of motor control could have effects like those that followed the development of corrective optics in the thirteenth century. In medieval Europe, the development of eyeglasses extended the productivity of artisans by freeing them from the farsightedness that often develops in middle age. Extending the productivity of people with motor disabilities could, likewise, benefit both the affected individuals and society as a whole.

Abstract

This article describes motor development in infancy and early childhood, especially highlighting the major motor skills in the first year of a child's life. The continuing development of motor skills in children means the acquisition of independence and the ability to adapt to the physical and social environment. Motor skills in posture horizontal, vertical, and locomotor skills allow the child greater body control and improvement of social skills and interaction. The motor behavior is the basis for the development of other skills throughout childhood.

Introduction

Child development is a complex interaction process of biological aspects with various environmental influences and experiences. Theories have been developed to explain how changes occur in the body of infants and in their ability to interact with the environment.

The continuing development of motor skills in children means the acquisition of independence and the ability to adapt to the physical and social environment. Motor skills and cognitive processes influence each other and are manifested mostly through behavioral motor modalities (Flehmig, 1992).

Theories of Motor Development

Regarding the evolution of knowledge about the study of child development, one can highlight the emergence of some theories that attempt to explain how the behavioral learning of the infant occurs from the prenatal period until the end of the sixth year of postnatal life. In this respect, the most studied theoretical frameworks are the neuromaturational theory (NT) and dynamical systems theory (DST).

The NT of motor development is the traditional model and remains the most frequently reported theory in textbooks about motor development (Gesell and Amatruda, 1945; McGraw, 1945). The central tenet proposes that changes in gross motor skills during infancy result solely from the neurological maturation of the central nervous system (CNS).

Advancements in the science of embryology led to the discovery that the embryo developed in a symmetrical manner, beginning from cephalocaudal and proximal to distal directions (Gesell and Amatruda, 1945; McGraw, 1945). From these observations, four assumptions have been formulated, which characterize the neuromaturational model: primitive movements for controlled movements, reflex activities for voluntary activities; motor development progresses in a cephalocaudal direction; movement is first controlled proximally and then distally; the sequence of motor development is consistent among infants; and the rate of motor development is consistent for each infant.

The DST emerged in the early 1980s as a new theoretical explanation for the changes that occur over time in motor behavior and motor skills of children (Thelen et al., 1987). The theoretical framework includes all areas of development, being derived from psychological theories, physics, chemistry, and mathematics. Researchers have postulated that when a new behavior is developing, it is dependent on an input of all contributions of the systems. This behavior may have characteristics that could not have been determined by the evolution of individual behaviors.

This observation was transferred to human movement by Bernstein (1967). He noted that the joints and muscles never work in isolation but with a coordinated synergy. It was postulated that the brain controls muscle groups better than individual units and that the muscle synergies themselves are able to autonomously modify an independent movement.

This theoretical approach also recognizes the maturational level of the CNS as an important component for success of the task, but it is not the only factor. Other variables influencing the final motor behavior include the emotional state of the infant, the degree of motivation, cognitive awareness, the infant's posture, muscle strength, and biomechanical leverages. The shape, size, and weight of the toy also determine how the motor skill is executed. In contrast to the neuromaturational model that recognizes only the influence of the cerebral cortex, the dynamic motor theory approach takes into consideration all of the factors impinging on the motor outcome (Thelen, 1989; Thelen et al., 1990).

In summary, the systems approach to motor development represents a holistic and advanced theoretical model. The infant, the environment, and the functional significance of the task cannot be isolated from each other because they represent a synthesized unit and the motor behavior observed as an output is a product of their interactions. The system is capable of autonomously modifying the motor skill, depending on the constraints imposed on the system and the level of functioning of each unit in the system. Elements composing the system can mature in different ways, and any single factor can act as rate limiting, delaying the emergence of a new motor skill (Thelen, 1995).

The theoretical framework presented here provides professionals who work with infants an opportunity to reassess the

traditional paradigm used to describe and understand the motor development.

Motor Skills in Infancy

The motor development of infants is divided into quarters or months, defining the motor behavior of the infants at each stage. However, these steps are not fixed and depend on the interaction with the infant's environment and experiences. The time in which the infant is able to perform various motor acts depends to some extent on the opportunities to rehearse them, varying according to the environment and the way the child was stimulated (Shepherd, 1995).

Each infant demonstrates his or her characteristic development pattern once inherent characteristics suffer constant influence of the interplay between child and environmental context. There is also considerable individual variation among children of different ages, as well as within the same age group. Yet, there are particular characteristics that allow an assessment of the level and quality of the performance (Gallahue et al., 2011).

The acquisition of motor skills is among the most remarkable achievements in the first years of life. Motor milestones such as the emergence of sitting without support or the first independent steps provide a framework for developmental monitoring of children in health supervision visits because these milestones belong to the most salient and best demarcated markers of developmental processes that parents and health care professionals can observe. In clinical practice, general pediatricians, child neurologists, and developmental professionals are often asked to predict future outcomes on the basis of early developmental milestones (Jenni et al., 2013).

Currently, motor development has been studied more as a process than as a product (Tani, 2005). In this sense, the idea of motor milestones does not offer a poor measure to know in detail the complexity of motor skills in the first years of a child's life (Adolph and Robinson, 2013). There is a recent trend in enhancing the quality and control of movements by the child than just whether or not this carries certain motor behavior. Moreover, one cannot fail to consider the cross-cultural influence on motor development. The rate of motor development may differ between children of different cultures, such as Chinese, African, or American. However, the product development appears to be similar and compatible among them (Karasik et al., 2010).

Despite the existence of motor milestones, when studying motor development of the child, it is necessary to verify the cultural context and not just follow Western standards of reference (Harkness et al., 2011). The professional or researcher should also give attention to the type of measuring instrument that is used for the evaluation of the child or parents or both. Each culture has its own organization, language, and habits of life. Therefore, not all instruments are easily applicable in all countries (Gladstone et al., 2009).

Considering the environmental characteristics in development, nutrition is also an important factor for healthy growth and development in childhood. The study by Angulo-Barroso et al. (2011) investigated the gross and fine motor development at 9 months of children from the urban area of China, Ghana, and the United States (African-American) who were iron deficient. The study revealed that African children had better performance in gross motor skills, such as standing with support and walking with support, and fine motor skills. These results are also supported by previous studies in which infants in Africa may have an advantage due to the early stimulation with balance and postural control that is typical of many cultures in Africa (Bril, 1986; Super, 1976; Werner, 1972; WHO Multicentre Growth Reference Study Group, 2006).

Regarding the screening for developmental disabilities, Bornstein and Hendricks (2013) conducted a survey of 172 000 families in 16 developing countries and concluded that developmental disabilities vary by child age and country, and younger children in developing countries with lower standards of living are more likely to screen positive for disabilities.

The development of children in the first year of life has been strongly marked by the explosion of gross motor skills. A device used in evaluating this age range has been the Alberta Infant Motor Scale (AIMS). This scale has been used in children in many cultures and has presented different results in their interpretation of early motor development. To Japanese children, the AIMS percentile ranks of motor development showed results below the expected range (Uesugi et al., 2009). In a study conducted in Brazil with 795 children between 0 and 18 months, the results were almost similar to the Japanese study, in which children had lower mean motor skills according to the standardization sample of the scale for most months evaluated in the first year of life (Saccani and Valentini, 2012). Fleuren et al. (2007) assessed 100 children and concluded that new percentiles should be defined for Netherlands because the motor performance scores they observed were below the Canadian standard. In contrast, Syrengelas et al. (2010) conducted a study with 424 full-term Greek infants and found that their development path was similar to that of the Canadian children, demonstrating that the AIMS reference values could be used without loss of important clinical information.

The study of Tripathi et al. (2008) compared the normal motor development scores of 300 children from Mangalore, India, between birth and 60 months of age, on the Peabody Developmental Motor Scales-2 (PDMS-2) with the normative scores provided with the instrument. The authors founded that the Indian children's scores varied with some differing from the normative sample, whereas others did not differ across age groups and the different subtests of the PDMS-2. The study concluded that it is not possible to develop assessment tools that are culturally sensitive across different geographical regions and environments, but it is necessary to evaluate the cultural sensitivity of such tests for use in a particular region and ethnic group, especially when these assessment tools are being used to diagnose and plan treatment for a child.

To study the development of children above 2 years of age, ethnic or cultural differences seem to be more related not only to motor development, exclusively, but also to other areas such as language, social and cognitive skills, product of the interaction between organism and social environment. In addition, each assessment tool for motor development has its

psychometric properties that need to be taken into account in the analysis of the infant motor development.

In the following, the motor development will be presented according to the process of skill acquisition in accordance with the body posture, rather than motor milestones at ages-keys.

Development in Prone and the Neck Control

In prone position, since the first days after birth the infant begins to lift the head, an act of protective head tilt that is designed to keep the mouth and the nose free. However, the infant demonstrates an improved ability to lift the head when held against the caregiver's shoulder than when lying on the mattress. This demonstrates that even early on, the movement becomes easier under ideal mechanical conditions.

The neonate who spends some time exercising in prone develops extensor muscle strength, and the ability to extend the head and trunk develops rapidly. Within a few weeks, the infant is able to activate the extensors of the neck and the upper portion with enough strength to lift the head and look around. Initially, the baby can lift the head to 45° at 2 months of age, reaching 90° at 3 months. At this age, the maintenance of the head in midline is possible by bilateral contraction of the paraspinal muscles (Bly, 1994).

By 3–4 months of age, the baby can lift the head and chest in prone and push himself up. As head control increases in the prone position, visual attention enhances and the infant can follow an object horizontally to 180°. At 5 months, the baby can keep the head upright and can roll from prone to supine position.

At 6 months of age, the baby can push up on the wrists in prone and begin to perform a new activity in this posture: the pivoting. Pivoting is when the baby moves in the frontal plan with spine lateral flexion, often influenced by visual interest. In this activity, the baby weight shifts on extended arms.

At 7 months, the baby can achieve extended-arm weight bearing and upper extremity weight lifting and reach for toys. There is good pelvic weight shifting and lower extremity dissociation. Increased trunk and pelvic-femoral controls enable the baby to assume quadruped and rock in this position. From 8 months of age on, the baby will experience changes in posture, and will rarely be static when in prone position (Bly, 1994).

Development in Supine and to Roll

At birth, the posture of the arms and legs is predominantly a flexion pattern and such a pattern predominates during the first weeks of life. In a few months, the pattern turns into semiflexion, extension, and finally a posture without a predominant pattern (Flehmig, 1992).

At 2 months of age, functional activities are still somewhat limited, consisting of active head turning and semicontrolled extremity movements. Visual attentiveness and visual reaching are two of the baby's most functional activities. At 2 months, the head is rarely in midline, which may be due to the increased cervical spine mobility. This rotation is accompanied by an increased head extension and chin lifting.

At 3 months of age, the baby demonstrates symmetry and midline head orientation. The upper extremities are often characterized by bilateral flexion, bilateral abduction, and external rotation. There is more alignment of the ribs because there is activation of the abdominal muscles. When the knees approach the chest from triple flexion, there is an increase in abdominal contraction that promotes the lowering of the ribs.

At 4 months, the baby can easily alternate between extension and flexion. Head and trunk symmetry, midline orientation, and bilateral symmetrical extremity movements are dominant and enable the development of coordination between the two sides of the body. At this age, the ocular control is becoming more refined as a result of increased head control and vice versa. The eyes are more active during reaching for objects, though the upper limbs still lack the coordination and control needed for reaching.

Visual 'fixing' increases head stability and ensures its proper orientation in space. The alternating symmetrical movements of the lower extremities and the alternating activation of trunk extensors and flexors facilitate anterior and posterior tilting of the pelvis. These pelvic movements will provide a basis for further normal development of lower extremity movements. The baby is also able to extend the elbows and reach hands to knees when the hips and knees are flexed (Bly, 1994).

At 5 months, the baby can actively roll from supine to side lying. The action is initiated with total symmetrical total flexion, similar to that of the fourth month, but when the baby reaches side lying, the symmetry changes to asymmetry. The lower leg extends while the top leg remains flexed, and the baby momentarily laterally rights the head (laterally flexing against gravity). The baby can bring the feet to the mouth and the hands to the feet, using the control of upper and lower extremities, which helps in the development of body awareness and tactile stimulation.

Increased control for lateral flexion allows the 6-month-old to shift weight in the trunk and pelvis and assume dissociated lower extremity position. This enables the baby to roll toward side lying and maintain the position there. Side lying is a more functional position for upper extremity use. The baby is also beginning to use the lateral and dissociated movements to lift into quadruped from prone. These dissociated lower extremity movements mobilize the lumbar and thoracic spine.

Mobility throughout the spine, pelvis, and knee joint is necessary to achieve reciprocal extremity movements of the extremities during locomotion. Up to 6 months, the baby can pull to sitting when holding the examiner's hand. The baby has sufficient antigravity control and synergistic flex control to flex and lift the head, arms, and legs independently. At the end of the sixth month, rolling from supine to prone is initiated by flexion, rotation, and lateral weight shift. These components occur most frequently in the head and the lower extremities (Piper and Darrah, 1994).

As mentioned in the earlier part of this article, motor development is not exactly the same for all children in all cultures. In terms of motor ability to roll, the study by Nelson et al. (2004) found that Hong Kong Chinese infants roll from supine to prone before they roll from prone to supine. Mean ages of rolling over were 5.1 months for supine to prone and

5.7 months for prone to supine. Age of rolling over from supine to prone was not influenced by usual sleep position, infant's sex, mother's intention to breast-feed infant, number of siblings, marital status, main daytime caregiver, or feeding method over 9 months.

Development of the Baby to Sit

Head support in the sitting position occurs at around 3 months of age. When pulled to sit, the baby uses the optical or cervical righting by fixing the eyes on the examiner as if to reinforce head stability. The upper extremities resist passive extension, being inconsistently active in assisting by pulling into elbow flexion. When elbow flexion occurs, it is usually observed during the first half of the movement. When the head becomes stable and flexes forward, active elbow flexion decreases. During pull to sit, asymmetrical reactions in the extremities are common.

When head and trunk control have improved, head movements do not disturb the balance. The baby will use bilateral scapular adduction to reinforce trunk stability. This response is needed for postural stability, and stability precedes hand use. The baby can visually track objects, but cannot catch it, and will fall forward if left unsupported. There is a minimal resistance in the hips, lumbar, and lower thoracic areas for forward bending. However, the head and upper trunk do respond and resist (Bly, 1994). When held by the forearms and pulled to sit, the baby has the optical righting reaction and tries to reinforce the head-righting ability by visually 'fixing' on the examiner. At the end of the movement, the baby stabilizes the sitting posture after passing through the erect vertical position (Gallahue et al., 2011).

At 5 months, the baby displays increasing balance between the flexors and extensors. Erect sitting at 5 months is possible only when the baby's hands are held or the trunk is supported. The baby can maintain trunk extension, the arms flexed forward, and the scapulae abducted.

The 6-month-old has sufficient trunk and hip control to sit erect without support and uses a ring position of the lower extremities for stability. The upper extremities are freed from the postural system and can be used for reaching, manipulation, or forward protective extension. When sitting, the baby has control of the head and trunk movements on the sagittal plane (flexion and extension). On the frontal and transverse planes, the baby has head control, but no trunk control. When the baby rotates the head, weight is shifted to the same side to which the head turns. This frequently causes the baby to fall to the side.

At 7 months, the baby can sit independently with the back and pelvis straight. Because of increased hip and trunk control, unsupported sitting is becoming a more functional position in which the baby can hold and manipulate toys. However, the baby does not yet have full sitting balance. Some babies at this age pull themselves to stand, accomplishing this by transitioning from quadruped to kneeling while leaning on furniture (Shepherd, 1995).

At 8 months, the baby may use the positional stability in sitting. The femoral-pelvic muscles and trunk muscles are sufficient to stabilize the posture. Consequently, the baby experiments with and uses a variety of lower extremity positions when sitting, such as ring sitting, side sitting, long sitting, and sitting in W position (Bly, 1994; Flehmig, 1992).

At 9 months, sitting is often a transitional state for babies as they continue to explore the environment actively. The baby can also transition to quadruped by rotating the trunk and pelvis over the femur. This transition requires marked pelvic-femoral mobility.

Static sitting is rare for 10-month-olds. When babies are quiet in sitting, they are usually eating or exploring a toy. They spend most of the time moving in and out of sitting, retrieving toys, and transporting them to a new location. Wide abduction of the legs is also possible during long sitting. This posture provides additional positional stability, but it requires marked mobility in the hip adductor muscles (Bly, 1994).

Between 11 and 12 months, the baby may be observed sitting quietly when engaged in dressing, eating, or a fine motor task. Trunk rotation occurs preferably through a greater range than in previous months, and does not interfere with sitting stability. Trunk rotation enables the baby to reach for objects at the side and behind.

Development of Manual Skills

The neonate is able to fixate and track an object briefly as well as track a face from side to side if it is close enough. According to Shepherd (1995), it is likely that the coordinated control of the eye and the hand, i.e., the ability to grasp and to observe the hand is the beginning of the hand functional use.

The audio-visual-cephalic coordinations are present in full-term neonates when they are around 2 months of age. Due to the palmar grip reflex, all neonates display closing of the hands. However, when they are around 2 months of age, grasping movements become more relaxed and more finger extension is observed. The child begins to acquire intersegmentar hand–mouth coordination from the first month of life, becoming more evident in the second month.

The first way to grasp (hand–object coordination) is with one hand, with the three ulnar fingers (fifth, ring, and index fingers) flexed against the palm, where the infant only grabs the object when it touches the hand.

At 3 months, the baby can bring hands together in midline (hand–hand coordination) and flex and reopen them. The grasp reflex is gradually inhibited and at around the fifth month the child can consciously drop the object. The coordination hand-handkerchief on the face, in which a diaper may be put on the baby's face and is withdrawn by him, begins at approximately 4 months of age and the coordination hand–foot is present at 6 months of age.

At 7 months, the infant can also achieve a grip hook pattern (hand grip without thumb opposition). The thumb and index finger participate in a radial-palmar grip and both hands can be used simultaneously. In the next phase of development, the baby will be able to pick up small objects using all fingers, as it is no longer necessary to compress the object against the palm.

Later, the child begins to use a pincer grasp formed by the thumb and index finger to pick up a small object. At 9 months, the child also displays a complete handgrip and does not return an object in order to explore it visually and tactically. At 12 months, the baby will return the object if requested, and up to this age most objects given to the child will be placed in the

mouth. From 9 months on, some babies eat independently with a spoon, but most do it at around 15 months of age (Bly, 1994).

Development of Quadruped Position and Crawling

The quadruped position begins to be experienced by the child some time before crawling, i.e., at around 6–7 months of age. According to Shepherd (1995), not every baby crawls, but for those who do, this method provides the primary means of locomotion to be rehearsed. Crawling requires the child to be capable of making adjustments in kneeling position supported on four points. At 7 months, the baby likes new discoveries and toys that move, as well as small objects and household utensils and initiates transitions from sitting to quadruped and also from prone to quadruped (Bly, 1994).

Once in quadruped, the baby can rock forward, backward, and sideways. Rocking requires sufficient back stability to permit scapular freedom and mobility. Rocking at first utilizes large movements with falling, then it changes to smaller movements without falling. Additionally, rocking provides vestibular, proprioceptive, and kinesthetic stimulation and strengthens the shoulder and hip muscles (Piper and Darrah, 1994).

Diament's studies (1976) indicate that crawling begins at 8 months of age. However, some babies begin to crawl before this age. At 8 months, the baby can move easily from sitting to quadruped, starting this transition flexing the leg and foot under the body. The other leg remains flexed, abducted, and externally rotated, providing stability to the pelvis. The trunk remains symmetrically extended, and movement occurs in the sagittal plane. Marked mobility of the hip joint is necessary for this transition. The ability to crawl is a very efficient way for the baby to move from one place to another. They use the reciprocal extremity movements, which require a diagonal and counterrotation control in the trunk. Crawling and its weight-lifting components provide varied input into the hands, which may contribute to the development of the palmar arches.

Between 7 and 8 months, the baby can roll over, creep, and crawl in a matter of seconds. By the ninth month, the baby has become quite proficient at crawling. Reciprocal extremity movements and trunk rotation continue to be used. Speed and control during crawling are quite refined. The baby can move at varied speeds and can quickly change directions. Crawling is the primary means of locomotion, and the baby uses this skill to explore the environment and to obtain and transport toys (Gallahue et al., 2011).

At 10 months, crawling and climbing are the main activities of the baby. These movements demonstrate and develop the baby's coordination between the trunk and the extremities. The baby now has greater motor and body awareness to maneuver the body over, around, or onto obstacles that may obstruct a toy. If babies encounter obstacles while crawling, they can continue their forward progression by climbing up onto or over the obstacle. Infants encounter obstacles of different weights, sizes, and stability and will thus be challenged to develop problem-solving repertoire through experimental behaviors.

Kneeling without external support is a common occurrence for the 10-month-old. Contraction of the quadriceps is needed to elevate the body. Hip extensors are needed to stabilize the trunk. The 10-month-old infant can easily transition into and play in half-kneeling. Assumption of this posture demonstrates the baby's increased control of lower extremity dissociation (Bly, 1994).

Development of the Baby to Stand and to Walk

Some authors report the onset of orthostatic position at 7 months of age (Diament, 1976). Thus, the child stands independently and is supported at 9 months, and stands unsupported at 11 months. At 10 months, the child is able to stand by holding on to furniture, assumes a wide base of support of the feet, and can go hand in hand with an adult, evolving to one-hand support. With the continuing environment exploration guided by the ability of moving around in space, primarily through creeping and crawling, motor skills to stand and walk begin. The ability of rising to stand requires good muscle activation of the legs and begin at 7 months, but with the help of the upper extremities.

Subsequently, at 8 months, hip control on weight bearing must be sufficient to initiate the weight shift and stabilize the pelvis as the other leg is freed to move. The pelvic-femoral muscles must dynamically stabilize the pelvis and femur in the vertical position, rotate the pelvis over the femur, and maintain external rotation of the weight-bearing leg. If the hip muscles maintain the hip in extension and external rotation, the weight will be transferred to the medial side of the foot. These lower extremity actions resemble and may be precursors to the support and balance phases of gait.

At 10 months, the upper extremities seem to be used more for balance when rising to stand. From half-kneeling, the baby shifts forward on the flexed leg, which demonstrates good concentric control in the quadriceps. Once in standing, the baby uses leg muscles and minimum attendance of one hand to control posture. The arms and hands are free for exploration and manipulation. This eventually enables the baby to stand without upper extremity support. The baby spontaneously relinquishes hand support when presented with a toy that requires two hands. For bilateral hand use to be successful, the baby must preadjust posture for stability. Increased ankle movements are noted in standing, especially active plantar flexion (Flehmig, 1992).

At 10 months, the ability to control their posture and lower extremities in standing enables them to continue to vary the cruising pattern. They may cruise sideways with lower extremity abduction as they did in previous months, or they may turn so that they can face the direction in which they are going. This causes the baby walk forward holding with one hand instead of walking to the side holding it with both hands. Motor planning skills are being developed and practiced in standing as well as in other activities.

At 11 months, standing without external support is a new accomplishment for the baby. It usually occurs automatically when babies become very interested in a toy and they want to hold or explore it with both hands. Wide abduction of the legs assures a wide, stable base of support. These postural adjustments occur automatically before the baby lets go of the hands. With practice, the baby's independence in walking increases quickly.

The development during infancy of independent upright walking is a long and arduous process that requires months

of experience to reach a full flexible and adaptable movement. From a biomechanical point of view, also the gait pattern can be changed depending on the child's experience of walking (Bonneuil and Bril, 2012).

During initial attempts at independent walking, the movement components tend to regress to those used in early supported walking. The baby assumes a wide base of support with the feet, abducts the arms, and flexes the elbows. The upper trunk fixing pattern that the baby uses depends on the goal. The most common pattern of shoulder elevation, scapular adduction, and elbow flexion is used when the baby's goals are more nonspecific, when the baby intends to grab a toy, for instance. Because balance is poor in early walking, the baby moves quickly and usually falls or is caught in the arms of a parent. This does not discourage the baby or the parents, and walking workouts are practiced until the baby is independent (Bly, 1994).

At 12 months, the baby can lower the body with or without external support. To do this, the baby shifts the weight posteriorly, as if sitting down. The baby flexes the hips and knees but not the ankles. The quadriceps, hip extensors, and abdominals are also active in maintaining control. If the weight is shifted posteriorly without the knees being flexed, the baby will fall to sitting.

Standing presents new postural challenges to the baby because the base of support is different. When the baby is sitting, the hips are the base of support. When the baby is standing, the baby's feet are the base of support. Initial postural stability can be achieved through toe curling.

Most babies walk independently by or during the 12th month. Early independent walking usually has the following characteristics: fast speed, short stride length, short step length, high cadence, short swing phase, wide base of support, and no reciprocal arm swing (Flehmig, 1992; Shepherd, 1995).

At around 13–14 months of age, children stand independently. A 15-month-old child can walk and move up the stairs while held by the hands. Toe-off impulse at gait while standing is achieved at about 16 months, and the lifting of the toes while in bipedalism is observed at 17 months of age.

At 18 months of age, the child can climb on a chair and sit, and can also run. These dates are not fixed and maybe some children do not go through the same developmental process of the groups studied by the authors. Therefore, the occurrence of unsupported walking before 12 months of age and shortly thereafter (around 14 months) can be considered within the normal range, taking into consideration that the child was a full-term newborn and has 'no signs' of neurological impairment.

The emergence of the gait is still motivating great discussion among the authors. The act of walking is related not only to the maturation of the nervous system, but also to sensory experiences, and cultural factors related to genetics (Adolph and Robinson, 2013). Every human being has a unique temperament and ability to perform the movements of locomotion and adaptation to the environment can also be related to the psychological characteristics of the developing child.

In addition, the performance of previous motor milestones can be related to the acquisition of independent walking. Study by Kimura-Ohba et al. (2011) examined the relationship between motor development milestones with the age of walking in 290 healthy and term infants born in the district of Osaka City, Japan. Three milestones (rolling over, sitting, and crawling) were observed in the laboratory in infants aged 4 and 9 months by a pediatrician and a developmental psychologist, and the age of walking was confirmed in questionnaires filled in by the parents at 18 and 27 months. The authors found those children who could roll over at 4 months, and sit and crawl at 9 months, walked earlier than children who could not roll over, sit, and crawl. With regard to crawling, children who were creeping had a 1-month delay in walking, and those who could not move forward had a 2-month delay compared to typical crawlers. On multiple regression analysis, these three milestones were positively associated with walking. The study concludes that the age and the patterns of sitting, crawling, and rolling over were all related to the age of independent walking among Japanese infants. Consideration of milestone definition and variations is essential in medical check-up.

Development of Motor Skills after Gait

After walking independently, the child progresses to other skills such as running, jumping, throwing, and receiving, in a successive progression from easier skills to the most difficult ones until being able to combine them all.

Walking has often been defined as the process of continuously losing and recovering balance in erect position. Once independent walking has been achieved, the child progresses rapidly to the elementary and mature stage of walking. The gait can be considered mature in a certain moment in the motor development of children between 4 and 7 years of age (Gallahue et al., 2011).

EDITOR IN CHIEF BIOGRAPHY

James D. Wright received his bachelor's degree in philosophy from Purdue University in 1969, a master's degree in sociology from the University of Wisconsin in 1970, and his PhD in sociology from Wisconsin in 1973. His first academic appointment was at the University of Massachusetts, Amherst, where he was promoted to Associate Professor in 1976 and to Full Professor in 1979. Most of his 15 years at Massachusetts were spent as Director, Associate Director, or Director of Research in the Social and Demographic Institute.

Wright left Massachusetts for Tulane University in New Orleans in 1988 where he served as the Charles and Leo Favrot Professor of Human Relations in Tulane's Department of Sociology. He also enjoyed a courtesy appointment in the Tulane School of Public Health, Department of Biostatistics and Epidemiology. He left Tulane in 2001 to become the Provost's Distinguished Research Professor of Sociology at the University of Central Florida. In 2003, he was named as the Director of the University's Institute for Social and Behavioral Sciences and in 2013, was designated as a UCF Pegasus Professor, the University's highest faculty honor.

Wright was the Editor in Chief of the scholarly journal *Social Science Research* from 1978 until 2014. His previous editing experience also includes a 20-year stint as editor of the Aldine de Gruyter book series *Social Institutions and Social Change*, two editions of the *Handbook of Survey Research* (Academic Press, 1983; Emerald Publishing, 2010), and service on the editorial boards of numerous journals. He is the author of 21 books and scholarly monographs on topics ranging from homelessness to research methods to NASCAR, and he has published more than 300 journal articles, book chapters, reviews, essays, and polemics. Wright lives with his wife Christine Stewart and their multiple dogs and cats in Winter Springs, Florida, where in his spare time he likes to cook fancy meals for large crowds.

PREFACE TO THE FIRST EDITION

Large and ambitious works such as the present Encyclopedia depend on countless instances of input, cooperation, and contextual support. Therefore, the editors in chief would like to express their gratitude to several institutions and individuals. Our most general thanks go to our respective home institutions, the Center for Advanced Study in the Behavioral Sciences, Stanford, and the Max Planck Institute for Human Development, Berlin. We are certain that without the effective infrastructures of these institutions and the rich collegial networks and intellectual climate they provide, implementing this Encyclopedia in such a short amount of time would not have been possible. In this context, we also need to mention that due to the administrative budgets provided to the editors in chief by the publisher, the financial strains on our home institutions were minimal. Such a situation may be a rarity in the modern world of scientific publishing where publishers often press scholars and institutions into taking on larger and larger shares of the publication enterprise.

Aside from the more than 4000 authors, our deepest thanks goes to the editors of the 39 sections, to whom we delegated many decisions at various stages, who were primarily responsible for developing the lists of articles and authors, and who stood as the main gatekeepers of scientific quality for the entries in their sections. As a group, the section editors displayed remarkable energy, intelligence, and tolerance for the inevitable frustrations of tending large numbers of authors over a long period of time. Because of the brevity of the acknowledgment of the main editorial coproducers here, we alert the reader to the list published as part of the front matter and the description of their extensive work we offer in the Introduction. We would also like to mention that one of our highly esteemed section editors, Franz Weinert, died unexpectedly during the last phases of his editorial work. For people who had the pleasure of knowing Franz Weinert, it comes as no surprise that he completed his editorial duties without ever complaining about the difficult health conditions he was facing. He was a gentleman and a distinguished scholar.

The International Advisors also gave wise counsel on several designated occasions, and a number of these scholars represented on the International Advisory Board took more initiative — always helpful — than we had originally asked. The International Advisory Board was particularly helpful in the process of choosing section editors. Some of its members assisted us ably as we attempted to make the Encyclopedia as international as possible and also in dealing with special problems that are part of a large project with close timelines. Thus, we remember a few occasions where members of the International Advisory Board helped us with their substantive and social competence to deal with matters of editorial disagreements. Because of the overall quality, collaborative spirit, and professional responsibility of our section editors, these events were rare indeed, but dealing with them required masterful and accelerated input. We appreciate the collegiality that members of the Board displayed when called upon in these special circumstances.

In addition, and as described in the Introduction, there was a host of esteemed colleagues who gave us advice on numerous questions such as author and editor selection, organizational matters, topics for entries, content and quality of selected articles, substantive and methodological niches to be covered, as well as last-minute author replacements. The number of such individuals is large indeed, and most likely, significantly larger than the list presented below. There were too many short, but nevertheless significant collaborative encounters that we likely did not deposit into our long-term memory or written documentation. We apologize for such oversights.

In this spirit, we appreciate the advice given in the three planning meetings in Stanford, Uppsala, and Dölln/Berlin by the following scholars: Peter Behrens, Burton Clark, Gordon Clark, Lorraine Daston, Meinolf Dierkes, Jean-Emile Gombert, Torsten Husén, Gérard Jorland, Ali Kazancigil, Wolfgang Klein, Gardner Lindzey, Renate

Mayntz, Andrew Pettigrew, Denis Phillips, Marc Richelle, Ursula M. Staudinger, Piotr Sztompka, Eskil Wadensjö, Björn Wittrock, and Robert Zajonc.

We would like to extend special thanks to Laura Stoker, who pinch-hit for Nelson Polsby (section editor for Political Science) who was unable to attend the meeting of section editors in April 1998; and to Linda Woodhead, Senior Lecturer in Religious Studies, Lancaster University, who assisted David Martin with editorial work at all phases for the section on Religious Studies.

We also acknowledge the help of scholars who advised Smelser and Baltes at the stage of pulling together the entry lists, proposing authors, and occasionally reviewing the content and quality of articles submitted.

Smelser thanks: Jeffrey Banks, Peter Bickel, Edgar Borgatta, Charles Camic, Jennifer Chatman, Jean Cohen, Michael Dear, Pierre Ducrey, Eckart Ehlers, Sylvie Faucheux, Steven Guteman, Frank Furstenberg, Helga Haftendorn, Peter Katzenstein, David Laibson, Stephan Lauritzen, Douglas McAdam, Eleanor Maccoby, Phyllis Mack, Cora Marrett, Douglas Massey, Donald Melnick, Harvey Molotch, Lincoln Moses, James Peacock, Trond Petersen, Andrew Pettigrew, Alejandro Portes, Matilda Riley, István Rév, John Roberts, Dorothy Ross, Rob Sampson, Fritz Scharpf, Melvin Seeman, James Short, Fritz Stern, Carol Swain, Ann Swidler, Ken'ichi Tominaga, Charles Tilly, Wolfgang van den Daele, Sidney Verba, Margaret Weir, Thomas Weisner, and Jennifer Wolch.

Baltes is very grateful to: Nancy Andreasen, Gerhard Arminger, André-Jean Arnaud, Jens Asendorpf, Jan Assmann, Margret Baltes (deceased), Jürgen Baumert, Peter Behrens, Manfred Bierwisch, Niels Birbaumer, Peter Bloßfeld, Walter Borman, Robert F. Boruch, Mark Bouton, Michael Bratmann, David Buss, Shelley Chaiken, Lorraine Daston, Juan Delius, Marvin Dunnette, Georg Elwert, Helmut Fend, Hans Fischer, Peter Frensch, Alexandra M. Freund, Dieter Frey, Jochen Frowein, Gerd Gigerenzer, Snait Gissis, Peter Gollwitzer, Ian G. Gotlib, David Gyori, Heinz Häfner, Helga Haftendorn, Giyoo Hatano, Adrienne Héritier, Theo Herrmann, Otfried Höffe, Ludger Honnefelder, Paul Hoyningen-Huene, James Huang, Günther Kaiser, Heidi Keller, Martina Kessel, Gábor Klaniczay, Wolf-Hagen Krauth, Achim Leschinsky, Karen Li, Shu-Chen Li, Ulman Lindenberger, Elizabeth Loftus, Gerd Lüer, Ingrid Lunt, Hans J. Markowitsch, Laura Martignon, Randolf Menzel, Dietmar Mieth, Susan Mineka, Setsuo Miyazawa, John R. Nesselroade, Claus Offe, Vimla Patel, Meinrad Perrez, Rosa Lynn Pinkus, Robert Plomin, Neville Postlethwaite, Thomas Rentsch, István Rév, Peter Roeder, Richard Rorty, Hubert Rottleuthner, Peter Schäfer, Heinz Schuler, Norbert Schwarz, Richard J. Shavelson, Joan E. Sieber, Burton Singer, Wolf Singer, Edward Smith, Hans Spada, Günter Spur, Rolf Steyer, Michael Stolleis, José Juan Toharia, LeRoy B. Walters, Elke U. Weber, Peter Weingart, and Reiner Wimmer.

There was one more group that played a special role in the editorial review (see also Introduction). Baltes was assisted by a team of colleagues who provided expert input to the section editors and to him during final review: Gregor Bachmann, Alexandra M. Freund, Judith Glück, Wolfgang Klein, Olaf Köller, Shu-Chen Li, Ulman Lindenberger, Ursula M. Staudinger, and Christine Windbichler. Their expertise in helping us to ensure quality is gratefully acknowledged.

The day-to-day organizational work of the editors in chief occurred at their respective research centers — the Center for Advanced Study in the Behavioral Sciences and the Max Planck Institute for Human Development in Berlin. Smelser singles out Julie Schumacher, his main assistant in the project, for her organization of the meeting of section editors, and her superb coordination of the flow of correspondence and manuscripts over several years. She remained firm when the rest of us were faltering, and displayed the greatest efficiency, intelligence, and good cheer. Smelser also relied on periodic help from Leslie Lindzey, Kathleen Much, Jane Kolmodin, and Anne Carpinetti. Michelle Williams of the University of California, Berkeley, served as his main editorial assistant for nearly 2 years, going over all entry manuscripts from the standpoint of readability, and carrying a great part of the cross-referencing work; her judgment was always the best, and Smelser is forever indebted to her.

At the Max Planck Institute for Human Development, and aside from Julia Delius (see below), Baltes expresses his deeply felt thanks to the main secretarial staff in his office (Helga Kaiser, Romy Schlüter, Conor Toomey) who during the preparation of this Encyclopedia took on larger shares of responsibilities for other projects and occasionally helped out when the editorial office was overloaded. More directly involved in the day-to-day operation of the Encyclopedia was Penny Motley, who efficiently functioned as project secretary during the planning phase. During the main phases of the project, it was Yvonne Bennett who was responsible for secretarial and organizational matters. She deserves much applause for her superb and efficient help in the day-to-day running of the editorial office, making sure that all manuscripts and proofs were processed quickly, and also for assisting with the organization of various meetings. Not least, Baltes thanks the administrative office of the Max Planck Institute, and there especially Nina Körner and Karin Marschlich, for their competent work in managing the project budget, as well as Sabine Norfolk who handled most of the numerous fax

transmissions with ever present smiles and friendliness. Finally, in the Berlin editorial office, thanks are also due to Susannah Goss for her excellent work in translating individual articles into English.

Individual section editors wish to thank the following scholars who gave them substantive advice in their work: Richard Abel, Itty Abraham, John Ambler, Karen Anderson, Mitchell Ash, Alan Baddeley, Boris Baltes, Manfred Bierwisch, Michael Bittman, Sophie Bowlby, John Carson, Shelly Chaiken, Roger Chartier, François Chazel, Stewart Clegg, Carol Colby, Philip Converse, James Curran, Jerry Davis, Natalie Z. Davis, Peter Dear, Juan Delius, Michael Dennis, Josh DeWind, Sherry Diamond, Elsa Dixler, Georg Elwert, Howard Erlanger, Drew Faust, Malcolm Feeley, Nancy Folbre, Michael Frese, Angela Friederici, Lawrence Friedman, Bryant Garth; Victor Ginsburgh; Marcial Godoy, Frances Goldscheider, Calvin Goldscheider, John H. Goldthorpe, Reginald Golledge, William Graziano, Stephen Gudeman, Mauro Guillen, Doug Guthrie, John Hagan, Eric Hershberg, Steve Heydemann, Stephen Hilgartner, Judith Howard, William Howell, Jill Jaeger, Bob Kagan, Joe Karaganis, Roger E. Kasperson, Ronald Kassimir, Robert W. Kates, Wolfgang Klein, Hans-Dieter Klingemann, Bert Kritzer, Kay Levine, Steven Lukes, Michael Lynch, Akin Mabogunje, Stuart Macaulay, Donald MacKenzie, David Magnusson, Michael McCann, Sally Merry, Peter Meusburger, Sieglinde Modell, John Monahan, Kevin Moore, Gerda Neyer, Hiroyuki Ninomiya, Jodi O'Brien, Eva Oesterberg, Mark Osiel, James L. Peacock, Susan Phillips, Trevor Pinch, Wolfgang Prinz, Sheri Ranis, Harry Reis, Estevao C. de Rezende Martins, Marc Richelle, Leila Rupp, Gigi Santow, Austin Sarat, Simon Schaffer, Linda Scott, Tim Shallice, Seteney Shami, Ronen Shamir, Susan Silbey, Wolf Singer, Sheila Slaughter, Gerhard Strube, Ursula M. Staudinger, J. Stengers, Stephen M. Stigler, Michael Stolleis, Mark Suchman, Denis Szabo, Verta Taylor, Ashley Timmer, David Trubek, Leslie Ungerleider, Don Van Arsdol, Jakob Vogel, Rita Vörg, Judy Wajcman, Mary Wegner, Wlodzimierz Wesolowski, Steve Wheatley, Björn Wittrock, and Vincent Wright (deceased).

Section editors also thanked the following persons for their research assistance: Pamela Anderson, Susan Augir, Anja Berkes, Chantale Bousquet, Aida Bilalbegović, John Clark, Susanne Dengler, Kathrine Derbyshire, Annie Devinant, Casey B.K. Dominguez, Barbara Dorney, Elizabeth Dowling, Tracey L. Dowdeswell, Carolyn Dymond, Debbie Fitch, Susannah Goss, Verhan Henderson, Andrew Hostetler, Gudrun Klein, Heike Kubisch, Angie Lam, Ellen Lee, Valerie Lenhart, Kay Levine, Allison Lynn, Helena Maravilla, Carol B. Marley, Marion Maruschak, Michael McClelland, Rhonda Moats, Birgit Möller, Katja Neumann, Linda Peterson, Justin Powell, Paul Price, Xandra Rarden, Chris Reiter, Deborah Sadowski, Heidi Schulze, Heidi Sestrich, Keith Smith, Judith Thompson, Karen Varilla, Stuart Vizard, Danelle Winship.

It is difficult to single out one person as especially helpful. Despite the risks involved, we would like to highlight one person (see also Introduction). As shown in the front matter, beginning in the second year of the planning phase, Julia Delius served as our scientific editorial assistant. For our internal process of editorial review and management, Julia Delius was the mastermind of editorial coordination. Her work was simply outstanding.

Finally, we express our thanks to several individuals at Elsevier publishers whose work was both essential and helpful to us throughout. Barbara Barrett started the ball rolling for the entire Encyclopedia project, and was a master at negotiating out the fundamental arrangements at the beginning. Geraldine Billingham, as executive editor, also played an important role in the development of the project, as well as carrying the heavy responsibility for ensuring that all the financial and operational aspects of the project were realized. She executed this work with directness, skill, and tact. Angela Greenwell coordinated the editorial process with dexterity, calmness, and good judgment. Three persons were responsible for monitoring the progress of entries from Elsevier's side: Michael Lax for a time at the beginning; Jayne Harrison, who carried an overwhelming load of manuscripts month after month, and Helen Collins, who was responsible for the equally demanding job of shepherding the manuscripts through the entire production process. Ruth Glynn skillfully and imaginatively masterminded the development of the electronic version within Science Direct. We know how much the success of the Encyclopedia has depended on these individuals and their staffs, and our appreciation and admiration is here recorded.

Our expressions of gratitude and respect for the authors, section editors, reviewers, counselors, and editorial team, however, are not meant to distract from our own responsibilities as editors in chief. Let us hasten to add, therefore, that those whom we acknowledge deserve most of the credit but little of the blame for whatever shortcomings remain.

Neil J. Smelser
Paul B. Baltes
Palo Alto and Berlin
June 2001

INTRODUCTION

Alan Sica's article in this encyclopedia observes, "The urge to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West" (Sica, 2015). Sica dates the origins of this urge to Plato's nephew Speusippus, who took up the challenge of Plato's call for an *encyclopedia* (from Greek words meaning 'general education'), and traces the urge though Pliny the Elder, Vincent of Beauvois, Francis Bacon, Denis Diderot, and a great many others. Today, an encyclopedia is simply a self-contained reference work "with two aims: to include up-to-date knowledge about a particular discipline or group of disciplines and to make this knowledge conveniently accessible" (Smelser and Baltes, 2001). Such are the aspirations of the present work.

Histories of the concept of an encyclopedia are widely available and need not occupy us here. Those interested in where the *International Encyclopedia of the Social and Behavioral Sciences* (IESBS) fits into the long history of encyclopedias will do well to consult the Sica article quoted above or the Smelser–Baltes 'Introduction' to the first edition of this work.

This is the second edition (2/e) of the IESBS. Elsewhere, I acknowledge my immense debt to the editors of the first edition, Dr Neil Smelser and Dr Paul Baltes. Without their perspective and template to follow in assembling the second edition, this version would have scarcely been possible. The very thought of an encyclopedia covering *all* the social and behavioral sciences, one that drew on scholars from *all* corners of the globe, is itself so audacious that one would hesitate even to begin without a pretty detailed road map to the terrain.

On the occasion of the publication of Robert E.L. Faris's widely acclaimed *Handbook of Modern Sociology*, Joseph Gittler was moved to ask, "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one." That question was posed almost 50 years ago; the ensuing half-century has been marked, as Sica says, by "an avalanche of reference materials the likes of which had never been seen in libraries prior to about 2000." So readers and critics are within their rights to ask: Why a second edition? Why now?

The first edition (1/e) was reviewed in *Contemporary Psychology* as "the largest corpus of knowledge about the social and behavioral sciences in existence" (Park, 2004). According to readily available data sources, IESBS 1/e has been cited nearly 6000 times in subsequent scholarly literature and has an h-index ($h = 24$) that would be the envy of many full professors. Citations are only one measure of impact, of course, and probably not the most important measure for a basic reference work intended more for students and a general audience than for practicing professionals. In addition to the thousands of scholarly citations, items from IESBS 1/e were 'hit' almost two *million* times on Science Direct between online publication in November 2002 and August 2014 — two million instances where IESBS 1/e was likely consulted as a basic reference source, to get quickly up to speed in a new area of research or to provide background for a paper or project, or just to satisfy a reader's curiosity. The first edition, in short, emerged soon after publication as a go-to reference work throughout the social and behavioral sciences. Michael Shanahan referred to the first edition as "the atomic bomb of reference works." It was thus an easy conclusion that the work had sufficient value to keep it alive and current.

In reading selected articles from the first edition, however, I was taken aback by how much and how quickly they had aged. The first articles I looked at were those pertinent to my own areas of research and in nearly every case, there was important recent work that I felt needed to be discussed. With the assistance of colleagues in other areas of the social and behavioral sciences, it became obvious that this was a general problem. To be sure, much of the material in 1/e has enduring value; indeed, roughly half the articles in 2/e are updated and revised items from the first edition. Still, it is sobering to realize just how quickly the frontiers of social science

knowledge shift and thus how quickly a basic reference source becomes dated. I am certain there are articles in the current edition that are already in need of some updating.

Smelser and Baltes enumerated six criteria that guided their decisions about what to include and what to leave out. The criteria are as follows:

1. secure knowledge, realizing that security of knowledge is a dynamic and relative term,
2. knowledge with balance and comprehensiveness,
3. knowledge that is integrative rather than fragmented,
4. knowledge that places the evidence into historical and theoretical context,
5. knowledge that highlights connections between topics and fields, and
6. knowledge that combines, where possible, theory and practice.

I would like to say I have followed these same criteria in determining the content of 2/e, but all six criteria have proved problematic in one or another way and thus deserve some comment in light of the present work:

1. What is secure knowledge today is apt to be recognized as wrong tomorrow. Many of our requests for updates to 1/e articles generated some response to the effect, "All of this is completely obsolete. We need to write a new entry from scratch." One would expect this to be true of areas of research such as behavioral genetics, say, or cognitive neuroscience or other fast-moving scientific fields, but it also turns out to be true of archaeology, history, and philosophy. The leading edge of research in *every* discipline threatens received wisdom; those who content themselves with received wisdom ('secure knowledge') will quickly find themselves behind the times. So our charge to authors was to focus less on the 'secure knowledge' in their respective fields and more on the cutting edge — the new perspectives, methods, findings, and issues that will animate social and behavioral science research in the coming decade.
2. Throughout the social sciences, the distinction between theory and ideology is sometimes difficult to discern, and so too the distinction between applied research and community or political activism. We need not invoke Max Weber's conclusions about the impossibility of a truly value-free social science to understand that ideological undertones and political preferences can often be detected in social science research work; sometimes, they are quite explicit. Nor is it much of a surprise to learn that many social scientists struggle, not always successfully, to distinguish between what they want the world to be and what the world in fact is. Such struggles are part of the process by which knowledge develops and are thus in evidence in many of the 2/e articles. It would be unwise to enforce by editorial fiat a consensus on issues that the social sciences themselves have yet to resolve.
3. The fragmentation of knowledge *across* disciplines is far more serious that the fragmentation of knowledge *within* them, although the latter is a problem as well. Many well-informed sociologists, for example, take pride in reading widely and can speak with some authority about what is going on in the field, even in areas of sociology that do not directly concern them. I assume this is also true of the other social and behavioral science disciplines and areas. But rare is the sociologist who is cognizant of work being done, say, in social geography *even when*, as is often the case, the fundamental problems, theoretical issues, and methodological approaches are similar. This is a widespread problem across the disciplines: The evolutionary psychologists do not know as much as they should about what the anthropologists are doing; the economists ignore a lot of pertinent work in sociology and political science; etc. For better or worse, disciplinary differentiation is an inherent element in the process of knowledge development and discovery, so this is a reality to be faced, not a problem to be solved. We dealt with this reality mainly in two ways: (1) Authors were encouraged wherever possible to think across rather than strictly within their disciplines. (2) Calling relevant work done in other disciplines to the reader's attention was a guiding principle for the choice of cross-references for each article.
4. Social-constructionist theories of knowledge would argue that knowledge does not become knowledge until it is placed in historical, cultural, social, political, and theoretical context. As put very simply and succinctly in the opening line of the famous text by Berger and Luckmann, "reality is socially constructed" (1966: 1). This is no less true of social science knowledge than knowledge in any other realm. Unfortunately, a great deal of what we think of as social science knowledge is based on biased samples of WEIRD people — that is, Western, Educated, Industrialized, Rich, and Democratic (Henrich et al., 2010). (The same point has, of course, been made by many others.) The WEIRD, thus defined, represent a rather exotic minority group judged by world standards, and the challenge for IESBS 2/e was therefore twofold: (1) to recruit non-WEIRD editors and authors where possible; and (2) to persuade all authors to incorporate comparative, cross-cultural, and

international themes and perspectives wherever it was possible to do so. This effort was more effective in some sections than in others. Moving away from nation-specific literature, themes, and results to a truly *international* (the I in IESBS) account of the social and behavioral sciences was an ever-present *desideratum* in my discussions with editors and authors.

Alas, an emphasis on cross-culturalism often brings to light that everything, or nearly everything, seems to vary by culture, subgroup, ethnicity or nation, and at that point the question arises whether social science generalization is even possible. Are there universals that cross all social groupings? Or does social science dissolve into a mist of group-specific particularities that adduce no general principles? That hardly seems desirable. Yet myopic and ethnocentric fixations on one's own society or culture are scarcely to be encouraged either.

The worst offenders in this regard tend to be social scientists from the USA (and from the West more generally), who, of course, also comprise the largest share of editors and authors for IESBS 2/e. True, as with greenhouse gases, the USA (and the West) also produce the largest share of the world's science, social and otherwise, and so it is inevitable that they also represent the largest share of IESBS 2/e contributors. The Swedish social anthropologist Ulf Hannerz wrote about this very issue in his marvelous essay, "Editing Anthropology" (Hannerz, 2010). Hannerz quotes a Canadian anthropologist who said of the "neighborly presence" of US anthropology that it was like being "in bed with the elephant." The same is true of most or all of the disciplines covered in this work. But then in a passage remarkable for both its insight and its generosity, Hannerz remarks, "No doubt tensions and conflicts may arise out of this situation, but perhaps it is better to understand that the elephant cannot help being an elephant, and that it makes sense for it, in its habitat, to behave in elephantine ways. A well-trained elephant, too, can do a lot of good, such as in carrying heavy loads." So if the elephant that is Western social and behavioral science has been pressed to carry the heavier load in these pages, that is, the price to be paid for being an elephant in the first place.

The larger issue here is that the social and behavioral sciences, which were largely birthed in the West, in Europe and the United States, mainly address a trans-Atlantic scientific dialogue, a dialogue that is carried out almost exclusively in English. Indeed, throughout much of the world, a scientist's stature is indexed in part by his or her success in publishing in English. Publications in the native language are simply *assumed* to be inferior. The main exceptions, tellingly, are French and German social scientists whose native-language publications are valorized. A Dutch or Portuguese or Hungarian social scientist who only published in the native language would be seriously punished in merit and tenure reviews. Elsevier's citation database Scopus *requires* English-language abstracts before a journal will even be considered for inclusion. And English (with American spellings) is likewise the official language of this encyclopedia. No resources were made available to get articles submitted in other languages translated (although several such articles were submitted). Inevitably, this biases the encyclopedia's coverage in favor of social science addressed to the trans-Atlantic dialogue. Consequently, a great deal of excellent social science published in Spanish, or Mandarin, or Farsi, or any of the other world languages, is overlooked.

That said, steps were taken to improve the internationalism of the encyclopedia's coverage throughout the 4 years of its development. To begin, I sought area and section editors from around the globe and urged them whenever possible to seek international (vs strictly Western) authors. Articles were often returned to their authors with explicit instructions to add international coverage. And when all efforts failed and we ended up with articles that were unmistakably restricted to a single nation in their coverage (frequently but not always, this was the US), I indicated the national focus in the article subtitle. Still, a great deal more WEIRD social and behavioral science remains in these pages than would be desirable in an *international* encyclopedia. In a later section, I give the national breakdown of everyone involved in this project.

5. An encyclopedia that "highlights connections between topics and fields" is easier to envision than to accomplish. Criterion (3) above speaks to the disciplinary fragmentation of our social science knowledge. William Easterly, the NYU economist, has written about the 'tyranny of experts' but the tyranny of the disciplines is an equal problem, a tyranny sanctified by the very academic structure of the modern university, where the separate and often warring colleges are each comprised of assorted departments, the latter representing basic academic disciplines. Interdisciplinary programs are almost invariably relegated to various centers, institutes, or specialized research laboratories — in short, to the periphery of the university's power structure. And while everyone *says* they want to encourage multi- and interdisciplinarity, very little is done to make that happen. Instead, departments remain as the fundamental unit of academic organization.

   Hortatory admonitions to editors and authors have made IESBS 2/e somewhat more interdisciplinary than its several predecessors, but in the end, the disciplinary emphasis in many of our articles would be hard

to overlook. Still, there are many sections of the work that were clearly developed with interdisciplinarity in mind and in which one finds interdisciplinary social science at its current best: environmental and ecological sciences; health; life course; sexuality; GLBT studies; public policy; evolutionary sciences; war, peace, violence, and conflict; and genetics, behavior, history, and society are a few sections that come immediately to mind.

I am particularly pleased with the extensive coverage given in 2/e to the interactions between the biological and social sciences. Harry Whitaker once remarked in a private e-mail that "we are all witnesses to the marriage of biology and the social sciences." Many of the articles found here are offspring of that marriage. And those articles leave little doubt that the future offspring of this marriage will be among the most exciting and insightful social science products of the coming decade.

The social sciences once resisted everything biological as rank reductionism; in addition, the social scientists have always feared that a mature and complete biology would eventually drive us out of business. Articles included in IESBS 2/e make it clear that 'nature' versus 'nurture' was the wrong question from the very beginning, that what we need to understand is how biological inheritance and social and cultural forces *interact* to produce individual and collective outcomes. This is where a lot of the interesting action in the social sciences is going to be in the coming years.

6. The coverage of the practical or applied sides of the various disciplines has been increased in this edition, so the applied content of 2/e certainly exceeds that of its predecessor. New to this edition is the entire section on applied social and behavioral sciences; also new is our large section on social work and the separate section on applied, industrial and organizational psychology. But as Sara Strickhouser and I say in our article on the history of applied social research, "The history of 'applied social science' is indeed the history of the social sciences themselves" (Strickhouser and Wright, 2015). All of the social sciences in their modern form were birthed in the post-Enlightenment effort to understand why people, their institutions and society as a whole were as they were — why greed was more visible than generosity, why oppression was more common than freedom, why inequalities of various sorts characterized every social institution. To the founders of the disciplines, the modern distinction between basic and applied scientific concerns would have seemed meaningless, as indeed it was.

The Planning Phase and Editorial Structure

Elsevier's original acquisitions editor for this project, Scott Bentley, discussed the broad outlines of our attack on IESBS 2/e with me in a series of phone calls in the early months of 2010. By May 2010, certain of these outlines had come into sharp relief. There would be a single editor in chief with a tier of 'responsible lieutenants' to assist. These lieutenants started out as advisory editors but soon morphed into the 10 area editors in the final editorial structure. Each area editor would in turn oversee various sections and each section would have its own editor or editors. The original plan was that the area editors would each be responsible for approximately 400 articles and each section editor responsible for about 100 articles, so that no one would have an excessive amount of work compared to everyone else. In the end, however, some sections required more articles and others fewer, so the areas vary from fewer than 300 to more than 600 articles, and the sections vary from fewer than 30 articles to well more than 200.

Prior to my first discussions with Scott Bentley, Elsevier had commissioned about 20 'market surveys,' roughly half from professional librarians and the other half from academics, each focused on 'what was right and what was wrong' with the first edition. The most insistent demand that surfaced was for a fully electronic, computer-searchable work either in addition to or instead of a print version. In the end, both an e-version and a print version are being made available. But there were also consistent concerns expressed about spotty coverage of some areas: no coverage of social work to speak of; inadequate coverage of accounting, marketing, and business; no separate section of criminology; haphazard coverage of applied topics and concerns; and so on. And there were the predictable concerns about undue Western domination of the work.

Working from the 1/e Table of Contents and this stack of 20 surveys, I tinkered for a few months with how best to expand coverage to address the concerns our reviewers had expressed; the result was (more or less) the editorial structure shown elsewhere in the front matter of this work. Thus, the 53 sections of 2/e are basically the 39 sections of the first edition plus sections that were added to cover important emerging areas of research interest (e.g., gay, lesbian, bisexual, and transsexual studies) or to provide deeper coverage of disciplines and subdisciplines that the first edition treated lightly if at all (applied social and behavioral sciences, social work). A

few of the first edition sections were eliminated entirely: specifically, integrative concepts and issues (something of a catch-all category for 1/e articles that were highly interdisciplinary or simply did not fit anywhere else) and gender studies (gender is now so thoroughly integrated into the research and thinking of all the social and behavioral science disciplines and subdisciplines that a separate section was unnecessary and somewhat retrograde). Others were altered or expanded in significant ways (organizational and management studies, for example, became the second edition section on management, organizations, business, marketing and finance; expressive forms evolved into the 2/e section on culture and the arts; linguistics was subdivided into three separate sections; etc.) And some subdisciplinary areas that were part of other sections in the first edition were given their own sections in the second (life course studies; sexuality; criminology; labor studies; and war, peace, violence, and conflict are the most prominent examples), just to ensure adequate coverage.

The Introduction to 1/e (Smelser and Baltes, 2001) discusses at great length the intellectual architecture of the first edition and its evolution; the agonizing decisions about rules for the biographical articles; whether to organize the work by discipline, by concept, by an a priori taxonomy of social science knowledge, or in some other manner; and related structural matters. What resulted in 1/e was something of a hybrid model with some sections clearly representing specific disciplines, others representing 'overarching topics,' still others representing 'intersecting fields,' and so on. My task was far less challenging: I thought the architecture of the first edition served its purposes admirably and so I adopted it wholesale for the second edition, with the small modifications noted above.

While each of the 53 sections of 2/e has some more or less obvious justifying logic or substantive or disciplinary coherence, their arrangement into the 10 areas of the second edition does not. As already indicated, decisions about what sections to include and exclude were made very early in the development of the second edition, based on what was in the first edition, what Elsevier's marketing surveys suggested as significant lacunae, and my own sense of things. The arrangement of the sections into areas came later and was dictated largely by the interests and expertise of those who had been persuaded to sign onto the enterprise. Thus, all the Linguistics sections are in Area Five along with the cognitive and neuroscience sections because Harry Whitaker at Northern Michigan University had been a linguist first, a neuroscientist second, and a historian of psychology third. Likewise, Area Eight contains its seemingly chaotic hodgepodge of evolutionary sciences, genetics, religious studies, science and technology studies, and law because these happen to be the fields of interest of the redoubtable Barbara Prainsack of King's College, London, whose editorial talents are as deep as her interests are broad. Simplifying only slightly, section editors were chosen for their substantive expertise in particular areas of research (as well as their international or cultural 'range'); the plan was that section editors would review each of their articles for completeness of coverage, currency, fairness, and the like. In contrast, area editors were chosen for their breadth of interest and knowledge spanning multiple sections – people who by nature, experience, and training would be good at seeing the big picture. The role of the area editors was to assure that the articles were at least modestly international and interdisciplinary and formed some sort of coherent whole.

As laid out in an early e-mail to one of the area editors, "In my mind, Advisory [Area] Editors are generalists and Section Editors are content specialists. The Section Editors need to bring breadth of knowledge to their responsibilities, of course, but the primary job requirement is expert understanding of the particular field or section. We need section editors who can commission pieces that adequately review past developments in the subject area, but who can also shape their portfolios to identify major unanswered questions and new research developments." This was the general model followed throughout the recruitment process.

The approach just sketched inevitably left a residual area made of up sections that none of the other area editors were willing or able to claim. That proved to be Area Ten. A very large number of scholars from various disciplines and world regions were approached about serving as the Area Ten Editor. All demurred until I approached Martin Bulmer of the University of Surrey, who served the project for about a year but was unable to continue and subsequently left the Board. So for the final year of the project, the editing of Area Ten was done mainly by me.

The online subject classification for IESBS 1/e did not correspond precisely to the sections of the first edition; the subject classifications listed articles by broad general topic regardless of which 1/e section developed them. So for the first year or so, my assistants and I labored to assign every 1/e topic to one of the 53 2/e sections. With 53 sections to populate with articles and about 4000 articles to classify, the process of assigning articles to unique sections occupied huge amounts of time and generated endlessly complicated spreadsheets. (After about a year of this, a document surfaced in the Elsevier archives that showed exactly where each 1/e article had originated.)

Along with populating the 2/e sections with articles, searching for area and section editors occupied a major part of the early going. The original idea was to identify the 10 area editors first and then enlist them in the

search for their section editors, but in fact, these processes were simultaneous and were about half-completed when the two planning meetings were held: the first in San Diego on 19 and 20 May 2011; the second in London on 5–7 June 2011. Although not part of the plan, the first meeting was mostly attended by area editors and the second, by section editors.

The agenda for both meetings was largely identical: achieve clarity on the respective roles of the various editors; solicit advice on filling the unfilled editorial slots; get buy-in on the project *mantra* (internationalism, interdisciplinarity, inclusiveness!); explain the relationship between the first and second editions (e.g., that all 1/e authors would be offered the opportunity to update their articles); explain the process of assigning articles to sections; and the like. In almost all cases, consensus was quickly forthcoming.

The largest substantive change in the second edition is the treatment of psychology. (Whether measured by students, practitioners, professors or programs, psychology is the largest of the social and behavioral sciences.) In the first edition, the whole of psychology was contained within four large sections: clinical and applied psychology; developmental, social, personality, and motivational psychology; cognitive psychology and cognitive science; and behavioral and cognitive neuroscience. Cognitive science and neuroscience are, of course, rapidly growing sectors of the psychological discipline and it seemed appropriate to devote an entire area of the second edition to them. This area contained seven separate sections (three of them devoted to linguistics). And the 'softer' psychological sciences were placed in a separate area comprised of eight sections (including psychiatry and social work). These changes were made to assure that 2/e had adequate coverage of the entire psychological enterprise (a concern that was raised in some of the reviews of 1/e).

The structure of the editorial team was developed to serve two purposes: first, to divide up the labor into manageable parts; and secondly, to assure that every article in the final product would be reviewed by at least three scholars: the respective section editor, area editor, and the editor in chief. Since we were all aware of one another's identities throughout, the review process was not blinded, but every article in this work has been thoroughly peer-reviewed and vetted. In many cases, these articles have been through four, five, six, or even more revisions before being accepted for inclusion in the work.

Recruiting Editors and Authors

IESBS 2/e faced two different recruiting tasks: recruiting editors and recruiting authors. As indicated elsewhere, the original plan was that I would recruit area editors largely from my own personal networks and they in turn would recruit their section editors. In practice, the process was much more convoluted. First off, many of my 'first choice' candidates were hesitant to involve themselves in such a daunting and ambitious project. In some cases, an initial agreement to come aboard was followed a few weeks or months later by withdrawal as the true scope of work came into sharper focus. Some people that I tried to recruit as area editors demurred but agreed to serve as section editors; in other cases, candidates for area editors were nominated by section editors. In a couple of cases, there was a complete team of section editors prior to the successful recruitment of a corresponding area editor. And so on. The process of assembling an editorial team for the project was by no means linear.

Personal networks – mine and those of the people I persuaded to sign on – were the largest single source of ideas for other editors, by far. But personal networks tend to follow disciplinary and national lines and become rather quickly exhausted. In selecting both editors and authors, it was of course essential that all relevant perspectives be covered and that the breadth of fields was adequately represented. So other sources of ideas were tapped: the expertise of the Major Reference Works team at Elsevier; editorial boards of leading journals in the respective fields; Google Scholar citation counts; the knowledge and networks of people who had been involved in preparing the first edition – basically, anywhere names of top scholars in particular areas could be located. I did not keep systematic track of the number of people approached, much less of the outcomes; but in reviewing my e-mail archives from the early period of the project, I probably asked (on average) somewhere between six and eight prospects before I found someone to agree (an average that was highly variable across the areas and sections).

In the initial plan, area editors would recruit their own section editors and the section editors would in turn recruit their own authors, but the reality was again different. Inevitably, my negotiations with prospective editors (both types) would often result in a declination of the editorial role but an offer to write an article on a particular topic (or topics), offers I readily accepted. So in some cases, I had committed authors of particular articles well before I had the corresponding section or area editor in place. And many of the section editors likewise leaned on their area editors and on me for author suggestions, contacts, and outreach. So all the editors

were involved in locating willing authors (and not coincidentally, in making suggestions for articles to be included in the final work).

No one was asked to keep precise statistics on how many authors were sought before an agreeable author was found. My sense is that the 2/e editors had a somewhat tougher time with this than the 1/e editors had (but on the other hand, the 2/e editors had all the 1/e authors to work with, which Smelser and Baltes certainly did not have). The 1/e editors report that about 60% of those invited to write articles agreed to do so on the first 'ask' (with equivalent success rates in each subsequent 'ask'). In 2/e (or so I would guess), the success rate was probably closer to 50% and possibly even lower. They also report that something in excess of 90% of those who agreed to write for 1/e in fact contributed "acceptable entries in time to be included…" In the 2/e case, we found ourselves still soliciting authors within a few weeks of the submission deadline and some dozens of authors pulled out of the project at the last minute. Still, when all the dust settled, there were just about 800 articles planned for both editions that never materialized and both editions ended up with just fewer than 4000 articles. Perhaps these are 'natural limits' for a work of this sort.

Biographies*

In the Introduction to 1/e, Smelser and Baltes provided a short history of and rationale for the decision to include a limited number of biographical articles (150 of them, to be exact). This was evidently a controversial and contested decision since some of those associated with 1/e felt that biographical articles had no place in an encyclopedia focused on substantive knowledge (versus the personalities of those who produced it). As Newton said (paraphrasing a passage from Bernard of Chartres), "If I have seen further, it is by standing on the shoulders of giants" (a passage made famous among social scientists by Robert K. Merton's *On the Shoulders of Giants* (1965)). In other words, discovery is only possible because its discoverer is able to refer to knowledge already gathered and accumulated by his or her predecessors; and since all discoveries – small and large, substantial and minor – contribute to the production and accumulation of knowledge, singling out particular scholars for special attention would be both pointless and invidious.

This position, although understandable, was abandoned in the first edition and remains so in the second, largely because it is not possible to understand the social sciences without knowing the individuals who contributed to it. C. Wright Mills once defined the sociological imagination as the intersection of biography and history (Mills, 1959). To know the social sciences therefore requires biographical and historical knowledge. The social sciences are distinguished from the physical and biological sciences in the way they produce knowledge because individual human beings, including social scientists, invest meaning in their actions. Only through understanding the meaning that individuals give to their actions are social scientists able to provide explanations of human behavior and its outcomes. And what applies to social action in general applies to the production of social science knowledge as well. It thus makes sense to include biographical accounts of social science personages who have been particularly distinguished in making sense of human action and have in turn made major contributions to social science knowledge. To acknowledge individual social scientists with biographical articles is also to acknowledge their special and particular insights.

Once the decision was made to include biographies in 1/e, the next major decision was whom to include and whom to leave out. Two arbitrary but defensible principles governed these decisions: (1) the total number of biographies was not to exceed 150 (chosen because it seemed like a manageable number) and (2) only biographies of the dead would be included. The 1/e section editor for biographies, Karl Ulrich Mayer, consulted handbooks and encyclopedias, asked other section editors to name and rank the most important names in their respective disciplines, ran citation checks, and finally submitted a consolidated list to various experts for review. This resulted in some additions and some deletions and in the end 147 biographies made it into the first edition.

Instructions to authors writing these biographies directed them to include "a brief sketch of the major dates and events in the life of the biographee," to describe "the major contours of the [person's] substantive contribution," and to highlight the "importance and relevance of the biographee's work for the social and behavioral sciences." Largely the same instructions were given to 2/e biographers.

The selection criteria for 2/e were very different. First, on the reasoning that well-done biographies of leading figures is one of the things that draw readers to a work such as this, the total number of biographies was

* My thanks to Andreas Hess for drafting this section of the Introduction.

increased by more than 100 (to just over 250). In a major departure from 1/e, much of the increase is made up of biographies of the living. The 1/e restriction that excluded living persons resulted in anomalies that we thought needed to be addressed. As life expectancy has expanded in the twentieth and twenty-first centuries, so have the life spans of social scientists. Claude Levi-Strauss, to cite one obvious example, lived to the age of 101 years. When 1/e was published, he was in his 90s, was widely cited, was recognized universally as a modern classic, indeed a genius, of social anthropology – and yet, owing simply to his longevity, he was not included in the 1/e biographies. Biographies of, for example, the economist Herbert Simon, the political economist Albert O. Hirschman, the sociologist and philosopher Jürgen Habermas, and the linguist Noam Chomsky were all excluded for the same reason; indeed, Habermas and Chomsky still live as this is being written (Fall, 2014). In all these cases, the major works had been produced decades earlier, their major imprints on the social and behavioral sciences were already evident, their eventual inclusion in works such as this was inevitable. Are readers to be deprived of accounts of their lives, times, and contributions just because they have survived into deep old age?

Once the decision was made to include biographies of the living, however, it was not always easy to decide who among the living merited inclusion. Often the editors had to make decisions on a case-by-case basis, frequently in extended consultation with colleagues or experts in the field. Criteria used to make these decisions were whether the potential biographee had a reputation beyond one culture, nation, or language group; whether there was a record of sustained production over several decades; and whether there was an impact beyond the confines of a single discipline. These criteria reduced our list of suggested biographees considerably. Early lists of candidates numbered as many as 200 new names (in addition to the 147 biographies included in 1/e). In the end, as noted earlier, somewhat more than 100 new names were added.

In a few cases, persons were included that arguably did not satisfy our inclusion criteria. One such is Raul Hilberg, who became famous mainly for having written one very important book, *The Destruction of the European Jews* (1961). Hilberg's book is still regarded as the seminal work in Holocaust studies, a field of research that came to prominence much later; we felt that his signal contributions to Holocaust studies merited a biographical article. Much the same could be said, perhaps, of André Gorz, a well-known social theorist from France, and Albert Memmi, whose work is on colonialism, anticolonialism, and racism. These and other examples could and probably will raise questions about the porousness of our criteria. Whether we were right in giving 'trespassers' their space is open to debate. In any case, whether Hilberg, Gorz, Memmi, and others do or do not merit their biographies is for readers, not us, to decide.

Other important changes in the 2/e biographies section include, first, a conscious effort to attain a better gender balance, including more women both as biographees and as authors; and second, expanding the biographies both geographically and culturally. In the end we made some inroads in both respects but fell short of our internal goals. One of the main reasons for this is that any encyclopedia must, in the first instance, be true to the disciplines it represents. This means being true to the real status of important players, their networks and disciplinary power relations, and their academic capital in their respective fields and beyond. Change in these respects has been noticeable; certainly, the growth of the social sciences in Asia has been remarkable; and in most disciplines, the proportional presence of women has increased. But modest change in the right direction does not a revolution make. Too many nonwhite, non-Western, and nonmale practitioners are still being left out on the disciplinary peripheries and are not fully represented – not in their home disciplines and not in our encyclopedia either.

We state this fact with regret. In many cases, the limiting factor is not excellence but simple visibility. Being part of the trans-Atlantic social science dialogue and engaging this dialog mainly in English translates into more visibility, as discussed earlier. This gets a scholar on the radar screen. Equally excellent work engaging other intellectual dialogues in languages other than English does not. A great many outstanding scholars have thus gone unrecognized in 2/e for precisely this reason. That being said, strenuous efforts were made to make the 2/e biographies more inclusive. Among those included are the Argentinean educationalist Sarmiento, the Brazilian sociologist Cardoso, and the Japanese political scientist Maruyama, to name just a few. This is, however, 'just a few' of the many dozens of prominent social and behavioral scientists 'out there' whom we would have included had we been given more time and more resources (to get non-English works translated, for example). We do feel that we have made some important inroads and beg the reader's understanding of the limits within which we worked. We can only hope that the next edition will strive for more inclusiveness and better representation than we were able to achieve.

Another entirely new feature in the 2/e biographies is the series of 'collective biographies.' In many instances, the intellectual lives of individuals who work in research groups intersect and form a network that makes the

entire group (or paradigm) successful. Examples include articles on the Durkheimians, the Annales School, the Frankfurt School, and several others.

As indicated earlier, instructions to authors were changed little from 1/e. All authors were asked (1) to include the most important biographical facts (country of origin, generation, education, influences, other formative experiences, networks, etc.); (2) to list the most important output (discoveries, publications, etc.) and to briefly discuss the subject matter and content of the most important publications or discoveries; (3) to look at the lasting impact of the person and his or her work (if possible, beyond just one discipline, language group, or culture); and (4) to provide a bibliography of primary and secondary sources related to the biographee and his or her work. Most authors stuck to these guidelines.

Finally, we state for the record that there are a number of important social and behavioral scientists that we would have liked to include but for whom we were unable to find a proper biographer. The search for biographers went on for nearly 4 years. In many cases, our first-choice author agreed at once, but in other cases, we approached four, five, or even more people before an agreeable author was found. And in about two dozen cases, no such author was ever found, with the result that a deserving person's biography had to be dropped. Forgoing a case-by-case discussion of these deletions, let it be simply noted that this is why we have not included biographies of people such as Amartya Sen, the economist and social philosopher; Raymond Boudon, the French sociologist; Ronald Dworkin, the legal theorist; Avishai Margalit, the philosopher; or a collective article for the British Marxist historians (Eric Hobsbawm, E.P. Thompson, Christopher Hill, and Perry Anderson). Perhaps our most regrettable omission is Neil Smelser himself, for whom no biographer could be found despite at least a dozen attempts. (Paul Baltes's biography is included.) Neil is one of the giants on whose shoulders we all stand.

Redundancy

I mentioned earlier that in the beginning of the project, there was no 'map' linking each of the 1/e articles to its respective 1/e Section. Our efforts to create such a map invariably bogged down every time we hit an article that could plausibly belong to any of several sections, which was often. Obviously, it would have been possible to force every article into a 2/e section, but at the time it seemed advisable to involve the editors themselves in these decisions. So on numerous occasions, I distributed lists of 'orphaned' articles (articles for which no home had yet been designated) to the area and section editors, asking for foster parents to volunteer. Eventually, of course, every article found a home, but at a relatively late date in the process, I became aware that a few dozen articles had found more than one home. That is, some of the editors adopted articles without filing the appropriate paperwork with the editor in chief! In such cases, the result was two articles on the 'same' topic. (The 2/e Table of Contents was scoured multiple times looking for precisely these kinds of duplications but in the end, several proved elusive.)

In the large majority of cases, the content of the 'duplicate' articles was sufficiently distinct that both articles were retained, often with some retitling to help readers differentiate between them. For example, readers will find two articles on 'social identity.' One was recruited for the section on social psychology; the other for the sociology section. With rare exception, the two articles discuss different aspects of social identity from entirely different disciplinary angles; indeed, the two articles share only a small handful of common references. So it was an easy decision to retain them both: one appears here as Social Identity in Social Psychology; the other as Social Identity in Sociology. Careful readers will find perhaps a score of similar cases in the encyclopedia.

Alas, in a few regrettable cases, the overlap between duplicate articles was so pronounced that one of the articles had to be deleted. Since by the time these problems surfaced the articles had (often) been written and rewritten several times and had been accepted by both the section and area editors, the last-minute decision to delete a redundant article was painful. My sincere apologies to the authors involved.

Some redundancy in a work of this scope and aspiration is not only inevitable, it is probably also desirable. A reader interested in, say, social inequality will (one hopes) want to know what the sociologists, anthropologists, economists, and geographers all have to say about that topic. And if a few of the many articles on the topic say more or less the same thing, then what harm is done? Editors at all levels were asked to be alert to redundancies across articles and the editorial record shows that many were. That being said, quite a bit of topical redundancy no doubt remains, and that is not (in general) a matter of concern. It is what Smelser and Baltes refer to as the "inevitable residue of overlapping."

The Review Process

Once the table of contents had stabilized, each of the editors was asked to review the 1/e articles assigned to their section or area and come to various decisions. In some cases, 1/e articles could be reprinted more or less 'as is,' with perhaps some updating of references for readers seeking entry points into the current literature. This was especially the case with what were eventually designated as 'legacy articles,' e.g., Gabriel Almond's article on Civic Culture, James Gregor's article on Dictatorship, &c. In other cases, the 1/e articles needed some updating to be suitable for 2/e, either by their original authors when available or by others recruited specifically for the purpose. The general rule was that all 1/e authors would be offered the opportunity to do the updates themselves, and that other authors would be sought in the event of the original authors' declinations. In still other cases, the 1/e article was so obsolete than an entirely new article would be required. And then finally, the review of 1/e articles often revealed areas of current research that were inadequately covered; in these cases too, completely new articles would be sought.

Where appropriate, the relationship between the 1/e and 2/e versions of an article is spelled out in the article tagline. In many cases, there were issues of authorship to resolve — a 1/e article written by *X* and completely revised by *Y* is *Y*'s article although *X* might be identified in the tagline; but what of an article written by *X*, now deceased, and only modestly revised and updated by *Y*? Every decision rule that I formulated to resolve such issues soon confronted an exceptional case where the rule did not seem to apply. So in the end, the only workable rule was that everyone should get proper credit for their intellectual property, whether prime author or reviser, whether living or dead. If exceptions to this rule have crept into the final product (as they almost certainly have), I offer my apologies to those whose work has been slighted or improperly recognized. Deciding on proper authorship for many of our articles was a far more involved and difficult task than expected.

The section editors formed the first line of editorial defense and were the ones to whom article drafts were originally submitted. The section editors read and commented upon the draft articles and returned them to authors for revision. It is a rare article that appears here in its original form: on average, articles were revised two or three times before being sent to the area editors and subsequently on to me; in many cases, it was more like five or six revisions, with subsequent revisions at the request of the area editors and the editor in chief. And in some cases, articles were submitted to outside readers for independent review. As I stated earlier, the reviewing process was not blind, but it was quite thorough, as is reflected in the exceptional quality of the final product.

Internationalism and Inclusivity

A truly *International* Encyclopedia of the Social and Behavioral Sciences would of course require a global network of editors and authors *and* a commitment to internationalize the content of the work wherever possible. With respect to the editorial team for 2/e, this was definitely realized. The section editors and editors in chief who produced the first edition were drawn from only nine countries: The United States, Germany, Italy, Canada, Sweden, Australia, France, Switzerland, and the UK. Two-thirds of those editors were from the USA and only 13% were women. Area and section editors for 2/e represent 21 countries, US scholars make up only 38% of the total, and women comprise 36%. Thus, the proportional representation of women among the editors was nearly tripled in 2/e over 1/e while the predominance of the USA was halved. Nations represented among the editors of 2/e that were not represented in 1/e include Luxembourg, Greece, Finland, Japan, China, Ireland, Singapore, Spain, Russia, Austria, Israel, and the Netherlands. The presence of several Asian nations on this list is particularly gratifying. To be sure, the North Americans and Western Europeans still predominate, but they no longer monopolize the field.

Adding the International Board of Consulting Editors (see the following statement of Acknowledgments) increases the internationalism of the editorial team even further. Of the 45 members of that Board, only 12 (27%) are US social and behavioral scientists. Countries represented on that Board that are not otherwise part of the editorial team include three Central and South American nations (Venezuela, Argentina, Costa Rica), several Asian nations (the Philippines, Malaysia, South Korea, India), a few Western European nations (Norway, Denmark), two representatives from Central and Eastern Europe (Hungary, Croatia), two from the Middle East (Lebanon, Qatar), and one from South Africa. These editions bring to 35 the total number of countries with representation on the IESBS editorial team.

Much the same can be said of the 2/e authors, who are also more international than the 1/e authors had been. Smelser and Baltes noted in their Introduction that while authors from 51 nations were represented in the work,

58% of the authors were from North America and another 35% were from (mainly Western) Europe. "As to gender composition, 21% of the [1/e] authors were women." In 2/e, the proportion of women among the authors has increased slightly to approximately 25% and the percentage of North American authors has declined to fewer than half. Again, North America and Western Europe still contribute the larger share of the 2/e authors but the growing representation of social and behavioral science authors outside the West is both noteworthy and encouraging.

Another important point is that the international scope of the project is much more pronounced than editors' and authors' current affiliations would lead one to conclude. (This would have been equally true in 1/e as well.) Consider, for example, Michiru Nagatsu, author of our article 03053 on the history of behavioral economics. Dr Nagatsu was born in Japan and retains Japanese citizenship but was educated at Exeter and the London School of Economics and Political Science and wrote his IESBS 2/e article while on a postdoctoral fellowship in Finland. Or Guillermina Jasso, area editor for Area Three. Jasso was born in the USA, received her PhD from Johns Hopkins, and is on the faculty at New York University. By any standard, she would count as a US sociologist in our compilations. Yet her parents were Mexican of Basque, Spanish, Portuguese, and Dutch origins; Spanish is her native language; over the course of her distinguished career, she has published with coauthors from Germany, India, Israel, Mexico, the Netherlands, and Sweden; and she holds a permanent research fellowship at IZA, the Institute for the Study of Labor, in Bonn, Germany. Scoring her as 'USA' scarcely does justice to her biography or to the international perspective she brought to the editorial task.

What is true of author Nagatsu and editor Jasso is true in degrees of virtually the entire roster of IESBS participants. If one includes place of birth, citizenship, where educated, sites of research, visiting appointments, sites of fellowships, honorary professorships, invited lectures, and on through the list of highlights in a modern academic career, it is safe to say that every nook and cranny of the globe (save, possibly, Antarctica) is represented somewhere in the biographies of IESBS authors and editors. The true measure of internationalism, in short, is not so much where people come from or where they currently are, but rather the extent to which they bring a sensitivity and commitment to cultural and national differences into their work. Whether this was or was not realized in 2/e is for readers to decide.

Concluding Observations

Smelser and Baltes aspired in the first edition of this work to "assemble the whole range of knowledge – vast and complex as it is – of the social and behavioral sciences in one place." Since what does and does not qualify as 'social and behavioral science' is itself contested, it is not surprising that nearly every one of the market reviews commissioned by Elsevier to guide the development of the current edition noted content omissions in 1/e that reduced its usefulness and that needed to be addressed in a second edition. Critics can and no doubt will say the same about 2/e. I have already mentioned the nearly 800 articles that appeared on the 2/e Table of Contents at one time or another but that will not be found in the final product, either because agreeable authors could not be located or (less often) because agreeable authors never produced an acceptable article. And it is pretty easy to identify whole chunks of present-day social and behavioral science that are given short shrift, or no shrift at all, in this work – not because these chunks were judged to be unimportant but because limits of time, space, resources, and networks meant that some elements of the contemporary social science enterprise never came to our attention.

The social and behavioral sciences begin with what artificial intelligence guru Marvin Minsky once described as a "three pound computer made out of meat" – the human brain, which for all we know is the most complicated three-pound hunk of matter in the universe – and end with a thoroughly globalized culture and social structure that encompasses all aspects of our species' physical, biological, psychological, social, emotional, cultural, and spiritual lives. We are the most successful species ever to have inhabited the planet; we have colonized every inhabitable piece of dirt; our range extends everywhere; all the earth's resources lay at our command. To record all that has come to be known about human origins, evolution, language, culture, and social structure – everything we know about human emotions, identity, love, religion, family, economics, politics, domination, exploitation, and on through a very long list – would require orders of magnitude more volumes than the mere 26 volumes that comprise the present work.

We have come increasingly to the realization that what is social and human about our species is very intimately connected to our biological, genetic, and evolutionary inheritance. At the same time, the brain specifically and biological evolution more generally "cannot be viewed separately from the material, historical and

social circumstances that produce it" (Berntsen and Baker, 2015). As these authors put it, biology and culture are 'mutually constitutive.' Fifteen years ago, the editors of the first edition remarked on "ferment at the boundaries between the biological and the behavioral and social sciences." And while there are still important controversies, much of the ferment has yielded to cooperation as we are just now beginning to explore this endlessly complex web of interconnectedness between our biological and social selves. It is an easy and nearly inevitable conclusion, thus, that the third edition of the IESBS will contain a great deal more of the work being done at this intersection than 2/e was able to accommodate.

To conclude on a purely personal note, the 5 years I have spent working on this project produced many professional and personal gratifications, none quite so delicious as the certain knowledge that I would learn something new every single day. My work on 2/e exposed me to literature I never knew existed and to aspects of the social and behavioral sciences of which I was at best dimly aware. I can only hope that readers who come to these pages will find them as enriching as I have.

ACKNOWLEDGMENTS

A work of this scale is inevitably a communal enterprise involving many hundreds of editors, authors, reviewers, technical support people, colleagues, professional acquaintances, and friends who have provided input, advice, encouragement, and assistance over the past five years. Any listing is bound to be incomplete, so my apologies in advance to those who expected to be mentioned here but are not. Be assured that the slight is not intentional.

My negotiations with Elsevier about this project began early in 2010. By May of that year, I had committed to the project and have been working on it at varying levels of intensity ever since — often on weekends, during holidays, and whenever else I could snatch a useable chunk of time. So my first acknowledgment must be to my wife Chris for suffering through my five year obsession, always with understanding and affection, usually with good cheer. Chris is probably the only person in the world who is happier than I am that the project is now completed.

I must also acknowledge an enormous intellectual debt to the editors in chief of the first edition of the *International Encyclopedia of the Social and Behavioral Sciences*, Drs Neil Smelser and Paul Baltes (the latter now deceased). Dr Smelser was gracious enough to serve as Chair Emeritus of the project's International Board of Consulting Editors and to put himself at my disposal as, in his words, "a battle-scarred veteran." The basic intellectual structure of this work is adopted more or less wholesale from the Smelser—Baltes edition, with a few exceptions noted earlier in the *Introduction*. Without the original to serve as the starting point and blueprint, it is hard to imagine even embarking on such a task, much less bringing it to completion. Their edition was hailed as "the largest corpus of knowledge about the social and behavioral sciences in existence," which is to say that it formed an *extremely* solid foundation from which to build the work you now hold in your hands.

The first edition was organized into 39 sections overseen by a team of 53 section editors. The structure of the second edition is slightly different. It is divided up into 10 broad 'Areas,' each with an Area Editor overseeing the work of between four and eight Section Editors. In all, the second edition is thus comprised of the 10 Areas subdivided into 53 Sections; the 53 Sections were developed by a team of 76 Section Editors. So whereas Smelser and Baltes had 53 colleagues to help complete the work, I had 84 (two of the Area Editors also edited their own sections). On pages i-v in the front matter to this work one finds an Editorial Board list showing the Area Editors, Section Editors, Sections, names, and affiliations of the entire editorial team — a team whose dedication and effort in behalf of the project has vastly exceeded the rate of pay. A more helpful, productive, or delightful group of scholarly collaborators is difficult to imagine.

What readers see in the listed Editorial Structure of the work is the *final* editorial team as it existed when the work went into production. As would be expected in a project of this duration, there was considerable turnover within the team as the project developed and as death, competing demands, and general indifference all took their toll. I am grateful, nonetheless, to everyone who agreed, at least initially, to participate in the project, whether or not they were able to stay involved to the very end.

Susan Hanson (Geography) and Ulf Hannerz (Anthropology) are owed a special note of thanks because, of the 53 Section Editors involved in the first edition, these are the only two who agreed to reprise their roles in the second. (Both also wisely requested and received coeditors to carry part of the load.) Persuading people to serve who had no real idea what they were getting into was challenge enough, but these two suffered through 1/e and were willing to do it all over again for 2/e. And for that, I am especially grateful.

Many of the editors benefitted from the assistance of colleagues and graduate students at their various institutions. There was no mechanism built into the editorial process to keep systematic track of this

assistance and so the listing below is certain to be incomplete. But I can at least acknowledge those of whom I am aware who contributed time and intellectual energy to the effort: Liam Morton and Andrea Livingstone (Psychiatry); Jennifer O'Connor and Alana Dorris (Applied, Industrial and Organizational Psychology); Jen Hanis-Martin (Sexuality); David Budde, Annette Stimmer, Nikolas Ott, and Franziska Pfeifer (Institutions and Infrastructure of Social and Behavioral Sciences); Matthew LeDuc and Scott Freeman (Contemporary Cultural Concerns); and Simone Dudziak (Public Policy). To those named, my thanks. To those omitted, my apologies.

A special note of thanks to Dr Donald J. Barrett. Don was originally recruited to develop an entirely new section of the second edition on Gay, Lesbian, Bisexual, and Transsexual Studies, completed the section in short order, then e-mailed me to ask if there was anything further he could do to be helpful. Consequently, he took a major hand in developing the section on Biographies and was quite helpful with many other sections too. He appears in the Editorial Structure both as a Section Editor and as a Senior Editorial Associate to acknowledge his yeoman service to the entire enterprise. Also listed as a Senior Editorial Associate is my colleague Dr Amy M. Donley, who has been with the project since the very beginning and who, more than once, was all that stood between me and madness. I am proud to count them both as colleagues, collaborators, and friends.

I am also pleased to acknowledge Don Barrett, Andreas Hess, Harry Whitaker, John Berry, Barbara Miller, Scott Bentley, and Claire Byrne for their incisive and helpful commentary on previous drafts of the Acknowledgments and Editor's Introduction.

The project's International Board of Consulting Editors, chaired by Smelser and Dr Peter Marsden of Harvard University, was formed late in 2011 as a 'sounding board' to be used by the Area and Section Editors in searching for topics and authors and to help push for greater internationalism in our coverage. As it turned out, several members of this Board also stepped up to write entries in their areas of expertise. The composition of this Board and the affiliations of the consulting editors (as they were when the Board was first formed, not necessarily as they are today) are as follows: Neil J. Smelser, *University of California, USA*; Peter V. Marsden, *Harvard University, USA*; Ronald F. Abler, *International Geographical Union, USA*; John Bacon-Shone, *University of Hong Kong, China*; Roberto Briceño-León, *Universidad Central de Venezuela, Venezuela*; Roel Bosker, *Rijksuniversiteit Groningen, The Netherlands*; Michael Burawoy, *University of California, Berkeley, USA*; Nestor T. Castro, *University of the Philippines, Philippines*; Dalton Conley, *New York University, USA*; Freek Cronjé, *North West University, South Africa*; Scott Davies, *McMaster University, Canada*; Abdul Rahman Haji Embong, *Malaysian Social Science Association, Malaysia*; Joan-Maria Esteban, *Barcelona Graduate School of Economics, Spain*; Robert S. Feldman, *University of Massachusetts, USA*; Sari Hanafi, *American University of Beirut, Lebanon*; Gudmund Hernes, *Norwegian Business School, Norway*; Sheila Jasanoff, *Harvard University, USA*; Tim Jensen, *University of Southern Denmark, Denmark*; Colin Jones, *University of London, UK*; Nadezhda Lebedeva, *Higher School of Economics; and National Research University, Russia*; Miklós Lévay, *Eötvös Lorand University, Hungary*; Dinka Marinovic Jerolimov, *Institute for Social Research, Croatia*; Laurie M. Joyner, *Rollins College, USA*; Ferenc Kiefer, *Hungarian Academy of Sciences, Hungary*; Pan Suk Kim, *Yonsei University, South Korea*; Katsuya Kodama, *International Peace Research Association; and Mie University, Japan*; Allan Lavell, *Facultad Latinoamericana de Ciencias Sociales (FLACSO), Costa Rica*; Jake Lynch, *University of Sydney, Australia*; Cecilia Mabragana, *Consejo Nacional de Investigaciones Cientificas y Tecnicas (CONICET), Argentina*; William McBride, *Purdue University, USA*; Ishwar Modi, *University of Rajasthan, India*; Leonardo Morlino, *School of Government, Italy*; Melvin L. Oliver, *University of California, USA*; Angela M. O'Rand, *Duke University, USA*; Kenneth Prewitt, *Columbia University, USA*; Thilo Rehren, *University College London Qatar, Qatar*; Colette Sabatier, *Université Victor Segalen, France*; Philip Schofield, *University College, UK*; Rainer K. Silbereisen, *University of Jena, Germany*; Chamhuri bin Siwar, *National University of Malaysia, Malaysia*; Tom W. Smith, *World Association for Public Opinion Research, USA*; Catalina Smulovitz, *Universidad Torcuato Di Tella Miñones, Argentina*; Philip Spinhoven, *Leiden University, The Netherlands*; Sukhadeo Thorat, *Indian Council of Social Science Research, India*; Nigel Thrift, *University of Warwick, UK*; John R. Townshend, *University of Maryland, USA*; Gisèle Yasmeen, *Social Sciences and Humanities Research Council of Canada, Canada*.

Searching for an editorial team to represent every social science discipline and every region of the globe quickly exposed the deficiencies in my personal network, so I am indebted to a very large number of scholars around the world for calling names of prospects to my attention, allowing me to drop their names in the recruitment effort, or otherwise helping me find people with the expertise and commitment required for the job. In most cases, this is a list of people who were invited onto the editorial team in some capacity,

demurred, but made valuable suggestions about others to contact. In several cases, people are listed because they engaged me in intellectual discussions about the structure, format, and even advisability of this work, or simply replied to a cold-call e-mail in pleasant, kind, helpful, or informative ways. Again ignoring the risk of omission, my sincere personal thanks to those named below for their contributions large and small to the final product:

Doug Anderton, Juri Allik, George Armelagos, Susan Ayers, Amanda Baumle, Janeen Baxter, Jess ben-Habib, Joao Biehl, David Blanchflower, Hans-Peter Blossfeld, Jason Boardman, Dorret Boomsma, Roel Bosker, Henry Brady, Martin Bulmer, Craig Calhoun, Miguel Centeno, William Cockerham, Mark Nathan Cohen, Amelie Constant, Simon Cottle, Connie Citro, Eileen Crimmons, James Curran, Scott Davies, Donatella Della Porta, George Downs, Francis Dodoo, David Dozois, Sonja Drobnick, Jaap Dronkers, John Dryzek, Riley Dunlap, Lauren Edelman, David Elesh, Paula England, Nancy Eisenberg, Geoffrey Evans, Miriam Faust, Robert Feenstra, Marcus Feldman, Stanley Feldman, Ronald Fischer, James Fowler, Jeremy Freese, Angela D. Friederici, Michael Frumpkin, Masahisa Fujita, Nicole M. Gage, Nancy Gallini, Rosemary Gartner, Morton Ann Gernsbacher, Robert Goodin, John Grattan, Lance Gravlee, David Greenberg, Wendy Griswold, Melanie Guldi, Monica Das Gupta, Peter Hatemi, Robert Haveman, Karen Heimer, John Hibbing, Sarah Blaffer Hrdy, Sheila Jasanoff, Kelly Kadera, Cigdem Kagitcibasi, David Kavanaugh, Roger Keil, Byungkook Kim, Rob Kitchin, Jack Knight, Lyle Konigsberg, Candace Kruttschnitt, Helen Ladd, Phillip Lane, Graeme Lang, Janet Lauritsen, Ashley Leeds, Evelyn Lehrer, Richard Lerner, David Lewis, Tim Liao, Tom Linneman, Norman Long, Karen Lyons, Ruth Mace, Gary Marks, Herbert Marsh, Karl-Ulrich Mayer, Lorraine Mazerolle, Rose McDermott, Susan Michie, Harry Minas, Peter Miller, S. Phillip Morgan, Victor Nee, Vin-Kim Nguyen, Paul Nieuwbeerta, Helga Nowotny, Howard Nusbaum, Claus Offe, Thomas Ollendick, Joan Orme, Dennis O'Rourke, Michael Overington, Catherine Panter-Brick, Susan Parnell, Deborah M. Pearsall, Gerard Pfann, Jon Pierre, Mike Ping, Jennifer Platt, Ken Prewitt, Cathy Price, Jill Quadnagno, Charles Ragin, Thilo Rehren, Ben Rosamond, Bo Rothstein, Beth Rubin, Heinrich Sauer, Peer Scheepers, Ralf Schwarzer, Moshe Semyonov, Michael Shanahan, Sara Shostak, Alan Sica, Rainer K. Silbereisen, Beth Simmons, Catalina Smulovitz, Michael Sobel, Diane Stone, Jill Stephenson, Rafe Stolzenberg, Miron Straf, Richard Swedberg, Alan C. Swedlund, Sidney Tarrow, Jacques-Francoise Thisse, Stefan Timmermans, Florencia Torche, Erik Tsang, Judy Treas, Billie Turner, Cees van der Eijk, Paul van Lange, James Vaupel, Karin Wahl-Jorgensen, Mitchell G. Weiss, Neil Whitehead, Pamela Wilcox, Bjorn Wittrock, Cornelia Woll, Gisele Yasmeen, and Barbie Zelizer.

Gratitude is owed as well to the many colleagues at Elsevier who contributed to the production of this volume. My first debt is to Claire Byrne, the project's Content Project Manager and the head of the Major Reference Works (MRW) team that managed the day-to-day *Sturm und Drang* of the project: aggrieved, confused, or delinquent authors, missed deadlines, testy and intransigent editors, and the often-maddening work style of the Editor in Chief. I am sure there were days when Claire wanted to tear her hair out, but to external appearances, she was an island of calm in a sea of turmoil. She was also exceptionally good at her job.

Claire's MRW team comprised Richard Berryman, Will Bowden-Green, Esmond Collins, Mark Harper, Sam Mahfoudh, Mike Nicholls, Gemma Tomalin, Joanne Williams, and Marise Willis. No matter what issue or problem I faced, one of these fine, capable people was always available to step up with a solution, invariably offered in a spirit of cooperation and good cheer. They have been to IESBS 2/e what tech support is to the modern computerized office. Getting this work completed without their help is inconceivable.

Thanks also to the succession of Elsevier's Acquisitions Editors who managed the finances and internal politics of the project: to Scott Bentley, whose gentle suasions pulled me into the project in the beginning; to Karen Maloney and Peter Labella who ran the show in the middle period; and to Lisa Tickner who was in charge at the very end. These are the people on the front line in the endless war between the publisher, who wants things done now and at minimal expense, and the Editor in Chief, who was always asking for more time and more money. The many dozens of amicable compromises necessary to bring the project to completion were all ably negotiated by Scott, Karen, Peter, and Lisa, and for that, I am grateful indeed.

The University of Central Florida and its Department of Sociology have provided a congenial home for the project. My thanks in particular to Dean Michael Johnson; to the current and former chairs of my department, Jana L. Jasinski and Libby Mustaine; to my faculty colleagues Liz Grauerholz, Phillip 'Hutch' Pollock, Bruce Wilson, Melanie Guldi, Stacy Barber, Tosha Dupras, and John Schultz; and to current and former graduate students Thomas Hall, Sara Strickhouser, Betsy Swart, Jordana Navarro, Marie Gualtieri, Shannon Simone, and Shannon Frey.

And most of all, my sincere thanks to the many thousands of authors whose work this is. When comparing the quality of the work contained within these pages to the authors' honoraria, it is obvious that IESBS 2/e is an act of collective charity by our authors to the disciplines they represent. It is my pleasure to thank our authors on behalf of the global social science community.

GUIDE TO USING THE ENCYCLOPEDIA

Structure of the Encyclopedia

The material in the Encyclopedia is arranged as a series of articles in alphabetical order.

There are four features to help you easily find the topic you are interested in an alphabetical contents list, cross-references to other relevant articles within each article, subject classification index, and a full subject index.

1. Alphabetical Contents List

The alphabetical contents list, which appears at the front of each volume, lists the articles in the order that they appear in that volume of the Encyclopedia. It includes both the volume number and the page number of each article.

2. Cross-references

All of the articles in the Encyclopedia have been cross-referenced. The cross-references, which appear at the end of an article as a See also list, serve three different functions:

a. To draw the reader's attention to related materials in other articles.
b. To indicate material that broadens and extends the scope of the article.
c. To indicate material that covers a topic in more depth.

3. Subject Classification Index

This index appears in Volume 26 and groups articles under subject headings that reflect the broad themes of Social and Behavioral Sciences. This index is useful for making quick connections between articles and locating the relevant article for a topic that is covered in more than one article. Under some section headings, you will find subheadings, if it is appropriate for the articles in a subject area to be grouped into more specific subareas.

4. Contributors

At the start of each volume, there is list of the authors who contributed to that volume.

5. Index

The index appears in Volume 26. The index includes page numbers for quick reference to the information you are looking for. The index articles differentiate between references to whole article, a part of an article, and a table or figure.

Movement Theory and Constraints in Syntax

C-T James Huang, Harvard University, Cambridge, MA, USA
Hiroki Narita, College of Industrial Technology, Nihon University, Chiba, Japan

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article discusses the considerations that motivate the postulation of movement transformations in generative linguistics, and traces the evolution of movement theory from the early days of transformational grammar through the development of trace theory, modularity, and Move α, to the contemporary theory of Internal Merge. It further describes the development of the theory of movement constraints, starting from the A-over-A Principle and construction-specific island constraints to various subsequent approaches, incorporating notions like cyclicity, headedness, traces, and economy. The notion of covert movement is also briefly reviewed, in light of the syntax–semantics interface and crosslinguistic parametric variations.

Movement in Syntactic Theory

Movement theory is a 'trademark' of Generative-Transformational Grammar (*see* Syntax (General); Generative Grammar; Linguistics: Incorporation). In this framework of natural language syntax, certain sentences are generated not just by combining words or phrases in some appropriate order, but also by moving them from one position to another. Thus the sentences in (1)–(3) are not constructed by directly 'merging' the leading items *will*, *what*, and *John* respectively at the sentence-initial position, but by first introducing them in their 'original' positions (marked by the blanks) and then fronting them to the initial position:

(1) *Will* John __ buy this toy?

(2) *What* has John put __ on the table?

(3) *John* was arrested __ yesterday.

In the Principles and Parameters Theory as implemented in the Government-and-Binding framework (Chomsky, 1981, 1986a,b), the computational system of a grammar generates underlying D(eep)-Structure (DS) representations in accordance with the X′ Theory that satisfy the selectional requirements of lexical items (*see* Valency and Argument Structure in Syntax), and transformational operations (particularly, movement operations) convert them to S(urface)-Structure (SS) representations. These SS representations are in turn mapped onto two levels that form the interfaces between grammar and other cognitive performance systems, PF (Phonetic Form) or PHON (phonetic interface) on the one hand and LF (Logical Form) or SEM (semantic interface) on the other (*see* Syntax–Semantics Interface). Thus for (2), the computational system will carry out movement operations (as indicated by the arrows) that turn its DS to its SS representation, as shown in Figure 1:

It has been assumed that the mappings in SS → PF and SS → LF also involve movement operations.

Figure 1 Tree diagram showing the derivation of 'What has John put on the table?'

Motivations for Movement

In some cases the postulation of movement can be justified by intuitive observations. The verbs *put* and *arrest* are transitive in traditional terms, requiring noun phrase (NP) objects following them (cf **John put on the table*; **Bill arrested*; an asterisk preceding a sentence indicates ungrammaticality). In (2) and (3), no NP object appears in the 'expected' postverbal position, despite their grammaticality. This paradox is explained if one says that *put* does have a postverbal object at DS, though the object is fronted at SS (as depicted in Figure 1). The postulation of movement thus enables one to preserve generalizations about the predicate–argument structure of verbs and other lexical items (*see* Valency and Argument Structure in Syntax) that explain grammatical well-formedness.

In other cases, the movement hypothesis has enabled generative syntacticians to unearth interesting phenomena that had escaped introspection in previous descriptions, and gain valuable insight into syntactic structure. For example, it is now widely assumed that, despite their surface similarity, derivation of (4a), but not of (4b), involves movement:

(4) a. Harry seemed to be honest.

b. Harry tried to be honest.

In particular, in (4a) but not (4b), the subject of the main verb *seem* originates as the subject of *be honest* and raises to the higher subject position at SS. Postulating Subject Raising in (4a) but not (4b) explains several differences between *seem*-type and *try*-type sentences that surface upon closer examination, e.g., the contrast between *The shit seems to be about to hit the fan* (under the idiomatic interpretation) but **The shit tries to be about to hit the fan*, etc. Similarly interesting facts have been addressed concerning examples like *Mary is likely to leave* versus *Mary is eager to leave* versus *Mary is easy to leave*.

Still in other cases, the existence of movement cannot be detected by intuitive observations of the type one can make concerning (1)–(3). One early rule, proposed in Chomsky (1955) and popularly known as Affix Hopping, concerned tense marking in English finite sentences. The fact is that tense marking seems to 'migrate' among auxiliary elements and the main verb: it may occur on a modal (*Monica* 'would' *sing*, but **Monica will sang*), on a perfective or progressive aspect (*Monica* 'has' *sung*, *Monica* 'is' *singing*, but **Monica have sings*, **Monica have is singing*, etc.), or directly on the main verb (*Monica* 'sang'). Traditional methods of 'immediate constituent analysis' would face difficulty in describing this range of phenomena in any simple way. Chomsky proposed treating the tense inflectional suffix as an independent syntactic item in DS representation (as the leftmost constituent of the Auxiliary) which, by Affix Hopping, 'docks' on whatever first auxiliary or verbal element follows it: thus, *Monica* PAST *will sing* → *Monica will*-PAST *sing* (=*Monica would sing*), *Monica* PAST *have+en sing* → *Monica have*-PAST *sing-en* (=*Monica had sung*), *Monica* PAST *sing* → *Monica sing*-PAST (=*Monica sang*), and so on. Affix Hopping vastly simplifies the grammar of tense marking, at the same time capturing the observed 'migration' (hopping) property insightfully.

The primary argument for movement is that it allows one to simplify grammatical descriptions, capture significant generalizations, and uncover deep insights into the nature of human language as a 'mirror of the mind.' Such considerations justify the movement hypothesis not only for more observable cases like (1)–(3) and (4a), but also many surprising or less obvious cases. (Some versions of generative syntax incorporate other devices to explain the 'movement phenomena,' including Lexical Functional Grammar Head-Driven Phrase Structure Grammar, Categorial Grammar, Dependency Grammar.)

Evolution of Movement Theory

Early Movement Theory

Chomsky's (1955, 1957) foundational work on English syntax led to a massive explosion of transformational generative studies of various languages and constructions. New syntactic phenomena were unearthed or became theoretically interesting to call for an analysis, and new rules were added to the repertoire of a grammar's transformational component. In addition to the aforementioned Affix Hopping, various other movement rules were also proposed, including Subject–Auxiliary Inversion (1), *Wh*-Movement (2), Passivization (3), Subject Raising (4a), as well as Relativization (5), Topicalization (6), *Tough*-Movement (7), Extraposition from NP (8), etc.

(5) This is the person *who* I have wanted to meet __ always.

(6) *This sort of movie*, I would never watch __.

(7) *John* is tough for us to deal with __.

(8) A book __ has just appeared *on syntactic theory*.

In order to ensure descriptive adequacy, each rule proposed was formulated in such a way as to (a) apply to only the input strings that meet a certain Structural Description (SD), (b) effect precisely the Structural Change (SC) as desired, and (c) only do so under any additional conditions as may be imposed. For example, the Passivization rule of English was defined in terms of the SD of an input structure that contains a postverbal object NP and the instruction for SC that it will (among other things) front the NP to the subject position. Additional conditions are noted for the applicability of the rule, among them the requirements that the main verb be put in the passive participle form, that the movement be carried out to an immediate local subject position, etc. Other rules were defined with similar explicitness and detail. Because the investigations were carried out in the generative (i.e., formal) approach, linguists working on syntactic phenomena were required to formulate precise hypotheses about the form and functioning of movement transformations. The explicit (and therefore falsifiable) formulations led to unprecedented expansion of our explicit knowledge of natural language syntax.

Modularity: From Rules to Principles

While the detailed formulations of movement rules helped ensure observational and descriptive adequacies of proposed grammatical descriptions, linguists increasingly realized that this was achieved at the cost of explanatory adequacy and conceptual beauty. For one thing, the detailed statement of each movement rule obscured the fact that many movement rules have similar properties. By repeatedly stipulating these properties in the statement of every rule, the theory became highly redundant and failed to capture the generality of such properties. In fact, some properties often included in the statement of movement rules are not peculiar to movement, but hold generally of other syntactic phenomena as well. To capture the correct generalizations, then, it was necessary to separate out general properties from the statement of specific rules.

One property of movement that was repeatedly stipulated in the formulation of each rule is that movement is generally *upward*, i.e., that it moves elements to a 'c-commanding' position. Defined in terms of tree diagrams like **Figure 1**, a node

α c-commands β iff neither α nor β dominates (contains) the other, and the first branching node dominating α dominates β. In **Figure 1**, each instance of movement is upward to a position c-commanding the original position. This 'upward movement requirement' should be stated once and for all movement rules, rather than separately for each rule. In fact, Chomsky (1975) noted that this requirement is but a special case of a more general principle that also governs anaphora in natural language. For example, the interpretation of a reflexive pronoun in English requires that it have an antecedent that c-commands it: *John criticized himself*, but **John's mother criticized himself* (the latter is ungrammatical because the intended antecedent *John* is not high enough to c-command *himself*). To capture this common property between movement and anaphora, Chomsky proposed that when a category is moved, it leaves a 'trace' behind, co-indexed with the moved category (as in *John*$_i$ *was arrested* t_i *yesterday* for (3)). The trace, being phonetically empty and having no inherent reference, depends on the moved category as its 'antecedent,' much as a reflexive depends on another NP for its reference. The 'upward movement requirement' thus reduces to a general requirement governing anaphoric dependency and may be eliminated from the statement of each movement rule.

Another common property of movement rules is that they operate only *locally*, as the following sections will show. Further, it has also been observed that movement typically operates in a 'structure-preserving' manner, so that a head (e.g., verb) can only move to a head position, an argument NP to an argument position (A-position), and an operator to an operator position (A′-position). (See again **Figure 1**, illustrating *has* undergoing head-movement, *John* undergoing A-movement, and *what* undergoing A′-movement.) The discovery of these and other general properties finally led linguists to the view that most details formerly attributed to individual rules should be dissociated from them and be ascribed to independent modules of the grammar with general applicability.

Generalizing Movement Operations: Move α and Internal Merge

One approach that culminated in the theory of Government and Binding (Chomsky, 1981) holds that all movement rules can be dispensed with, in favor of a single rule of maximal generality: Move α, α a category. This operation can apply freely and dislocate anything anywhere, irrespective of specific properties of the moving element and the target site, while the well-formedness of the output is to be determined by the other modules of Universal Grammar, such as the aforementioned principles of anaphoric dependency and structure preservation, as well as the locality constraints to be discussed in the 'Constraints on Movement' section.

An even simpler theory of movement, advocated in the contemporary literature, is to further reduce Move α to a special case of the general structure-building operation Merge. Merge is an elementary combinatory operation that recursively combines two syntactic objects, α and β, and forms a constituent comprising of them, thus Merge(α, β) = [α β] (or more precisely a set of α and β, {α, β}, with the label specified in some way or the other; see Chomsky, 1995 *et seq*). One mode of Merge, called External Merge, iteratively combines two independent objects, external to each other, and serves to generate basic structures of sentences from the bottom up. A sample Merge-based derivation of a sentence is given in (9). External Merge is specifically exemplified in (9a–d,f). Moreover, assuming that Merge can apply freely, it may also combine two syntactic objects α, β that are *not* independent of each other, that is, two objects one of which, say α, is internal to the other object β. This mode of Merge-application, called Internal Merge, is exemplified by (9e) and (9g). The underscore marks the relevant α internal to β. As indicated by indices, Internal Merge yields two copies (occurrences) of α, one within β and the other to the edge of β.

(9) A Merge-based derivation of *the apple, John will eat* ___.

a. Merge(the, apple) = [the apple]

b. Merge(eat, [the apple]) = [eat [the apple]]

c. Merge(John, [eat [the apple]]) = [John [eat [the apple]]]

d. Merge(will, [John [eat [the apple]]]) = [will [John [eat [the apple]]]]

e. Merge (*John*, [will [*John* [eat [the apple]]]]) = [John$_i$ [will [John$_i$ [eat [the apple]]]]]

f. Merge(C, [John$_i$ [will [John$_i$ [eat [the apple]]]]]) = [C, [John$_i$ [will [John$_i$ [eat [the apple]]]]]]

g. Merge(*[the apple]*, [C, [John$_i$ [will [John$_i$ [eat *[the apple]*]]]]]) = [[the apple]$_j$, [C, [John$_i$ [will [John$_i$ [eat [the apple]$_j$]]]]]]

Assuming that they undergo deletion at the phonological component, lower copies created by Internal Merge can be thought of as equivalent to traces of earlier movement transformations (the copy theory of movement, replacing the earlier trace theory of movement mentioned above). Thus, applications of Internal Merge in (9e) and (9g) correspond to A-movement of *John* and A′-movement (topicalization) of *the apple*, respectively. In this manner, the contemporary framework of Merge-based syntax (called the theory of bare phrase structure; see Chomsky, 1995 *et seq*) provides a unified theory of bottom-up structure building and movement transformations, incorporating the effect of Move α as a special case of Merge, a further simplification of Universal Grammar.

So long as these highly modular approaches to movement are proven to be successful, there is little or nothing left to do in the formulation of the movement rule itself. Consequently, increasing attention has shifted to the study of other modules of grammar, in particular the study of general locality constraints on movement and on the distribution of empty categories (traces) created by movement.

Constraints on Movement

In generative linguistics, a grammar G of a given language L is a hypothesis about the linguistic phenotype of the speakers of L. Such a hypothesis is descriptively adequate only if it defines all and only the (potential and actual) grammatical sentences of the language. A general linguistic theory or Universal Grammar, a hypothesis of the human linguistic genotype, is likewise adequate only if it defines all and only the possible grammars that are descriptively adequate. In the early stages of generative grammar study, linguists were primarily occupied with providing their grammars with enough descriptive powers to generate all grammatical sentences. In subsequent developments up to the present time, however, major attention has been directed toward restricting the expressive powers of their grammars. The study of movement constraints was motivated not only on empirical grounds of descriptive and explanatory adequacy, but also because it has proven a very productive probe into the nature of the human language faculty.

The A-over-A Principle and Ross's Island Constraints

The need for a general, powerful constraint on movement rules was noted quite early by Chomsky (1964), who proposed the A-over-A Principle to exclude movement of a phrase out of a larger phrase of the same type. The importance of movement constraints gained widespread attention with the emergence of Ross (1967), who showed the A-over-A Principle to be inadequate and proposed, in its place, a module of grammar containing a set of 'island constraints.' According to Ross, although movement rules may appear to displace constituents over an arbitrary distance (e.g., *What$_i$ did Harry say that Maria bought t_i?*), they must be sharply constrained so as not to extract elements out of certain domains that he called 'islands.' The following examples respectively illustrate Ross's island constraints (in each case the relevant 'island' is marked by square brackets): Coordinate Structure Constraint (CSC), Complex NP Constraint (CNPC), and Sentential Subject Condition (SSC). Other familiar constraints include the Subject Condition (SC), the Adjunct Condition (AC), and the *Wh*-Island Condition (WIC):

(10) *What$_i$ did [Harry buy t_i and Maria buy a pencil]? (CSC)

(11) *What$_i$ did Harry talk to [the woman who bought t_i]? (CNPC)

(12) *What$_i$ was [that Maria had bought t_i] surprising? (SSC)

(13) *Who$_i$ did [a picture to t_i] please you? (SC)

(14) ?*What$_i$ did Harry go home [before Maria bought t_i]? (AC)

(15) ?*What$_i$ did Harry wonder [who bought t_i]? (WIC)

The Ross-style constraints properly restrict the applicability of movement, but, as given, they amounted to a list of environments that form 'islands' to the exclusion of those that do not, and thus failed to explain their clustering. To overcome this problem, subsequent research has focused on how such idiosyncratic constraints can be reduced to a more natural set of general principles. Four types of approaches can be identified in this research endeavor, to which we turn one by one.

Cyclicity-Based Accounts: Subjacency, Barriers, and Phases

Chomsky (1973) proposed that most of Ross's island constraints can be subsumed under a general constraint dubbed the Subjacency Condition, which prohibits extraction of a constituent across two or more bounding (i.e., cyclic) nodes, defined as NP or S (the latter corresponding to IP under the generalized X-bar theory of Chomsky (1986b). The theory of Subjacency not only provided a unified account of CSC, CNPC, SSC, and WIC among others (see Chomsky, 1973 for details), but it also put forward the idea that syntactic operations (movement among others) are fundamentally governed by the principle of strict cycle: grammatical rules first operate within the smallest (most deeply embedded) cycle and then apply to successively larger dominating cycles. Under this cyclic model, long-distance dependency (e.g., interclausal movement) can be established only successive-cyclically, spanning over at most one bounding node at a time.

The cyclicity-based approach continued in Chomsky (1986b), where the notion of *barrierhood* was proposed to unify various conditions on movement and other linguistic relations (government, binding, etc.). In the *Barriers* model, movement is allowed to cross at most one barrier at a time, deriving the effect of Subjacency and Huang's (1982) Condition on Extraction Domain (see the 'Headedness-Based Accounts: Condition on Extraction Domain and Its Reformulations' section) while overcoming most of the shortcomings of these earlier proposals. The *Barriers* framework also provided a tool for measuring the degree of (un)grammaticality in incremental terms, capturing the fact that a movement crossing n barriers produces worse results than one that crosses $n - 1$ barriers. In this manner, various constraints defined in terms of barrierhood collectively derive the cyclicity of syntactic computation, whereby the grammar selects movement and other operations that are local, or as local as possible.

The notion of 'strict' cyclicity is further incorporated into the contemporary framework of Phase Theory (Chomsky, 2000, 2001, 2004, 2007, 2008; see also Uriagereka, 1999; Narita, 2014; to be discussed in the 'Headedness-Based Accounts: Condition on Extraction Domain and Its Reformulations' section). It holds that each syntactic derivation is partitioned into a set of smaller periodic units called 'phases,' basically corresponding to clauses (CPs) and transitive verb phrases (v*Ps). Once completed, past phases are eliminated from the derivational workspace and subjected to semantic and phonetic interpretation, and thereby become inaccessible for further computation (Phase-Impenetrability Condition (PIC)). Movement and other syntactic operations should therefore apply phase by phase, yielding the effect of successive cyclicity.

Headedness-Based Accounts: Condition on Extraction Domain and Its Reformulations

The second type of approach to movement constraints capitalizes on the headedness (or endocentricity) of phrase structure. According to the traditional X-bar theory (see, e.g., Chomsky, 1986a,b), every phrase is understood as a 'projection' of some designated lexical item (an atomic element drawn directly from the lexicon), which is called its 'head': thus, NP is a projection of an N, CP is a projection of a complementizer (C), etc. The X-bar theory further defines several structural positions within an XP for each head X. For example, the 'complement' of X is the sister of X: the object NP is the complement of V within $[_{VP}$ V NP] etc. Further, all other phrases within XP are called noncomplements, and specifically, the noncomplement that is immediately dominated (contained) by XP is called the 'specifier' of X: in Chomsky's (1986b) system where the traditional label S(entence) is replaced with 'Infl(ection) Phrase (IP),' the subject NP located within $[_{IP}$ NP $[_{I'}$ I VP]] (with I′ an intermediate projection of I) is called the specifier of I. Finally, all noncomplements that are not specifiers of some head are called 'adjuncts.'

Huang (1982) argued that the SSC, SC, and AC (12)–(14) reflect a general complement versus noncomplement asymmetry and are best subsumed under one general Condition on Extraction Domain (CED), which holds that extraction is possible only from 'properly governed' domains, i.e., complements (see also Kayne, 1981). This condition precludes extraction from noncomplements like specifiers (including subjects) and adjuncts, explaining (12)–(14).

While the notion of government (and proper government) played a pivotal role in the Government-and-Binding framework (Chomsky, 1981, 1986a,b), subsequent studies have tried to dispense with this notion in favor of a maximally simplified theory of Universal Grammar in line with the Minimalist Program (see Chomsky, 1995). As a result, much research has been devoted to possible refinements and reformulations of Huang's CED-based account. One such approach was advocated by Uriagereka's (1999) cyclic Spell-Out model. This theory proposes a unidirectional left-to-right head-complement branching pattern *à la* Kayne (1994), and argues that any structure that deviates from such head-complement recursion, i.e., phrasal specifiers and adjuncts, must be subjected to Spell-Out (mapping to phonetic interpretation) and reduced to a unitary headlike element ('gigantic compound' in Uriagereka's terms). Cyclic application of Spell-Out was assumed to render each noncomplement opaque to further computation (an assumption akin to Chomsky's PIC discussed in the 'Cyclicity-Based Accounts: Subjacency, Barriers, and Phases' section), which successfully accounts for their islandhood without recourse to proper government. However, Uriagereka's theory necessarily implies a strict universal noncomplement–head-complement word order, which poses an insurmountable problem in accounting for cases involving head-final word orders or right-adjunction in various languages. For this matter, Narita (2014) proposes an alternative conception of recursive head-complement branching that is akin to Uriagereka's but free from stipulations on word order. Narita's approach reconciles the basic insights of Huang's CED, Uriagereka's cyclic Spell-Out and Chomsky's PIC, while it also provides some account of certain exceptions to the effects of SC and AC.

Trace-Based Accounts: Empty Category Principle

The third type of movement constraints has to do with the distribution of movement traces. In the earlier framework, proper government played a crucial role in constraining not only extraction *from* subjects and adjuncts (as in CED; see the 'Headedness-Based Accounts: Condition on Extraction Domain and Its Reformulations' section) but also extraction *of* subjects and adjuncts. Sentences (15)–(16) exemplify cases where *long* extraction of a subject or an adjunct is prohibited:

(15) *This is the person who_i John wondered [whether t_i would fix the car].

(16) *This is how_i John wondered [whether Bill would fix the car t_i].

These cases were accounted for by the Empty Category Principle (ECP), which requires that a trace not be separated from its governor by any barrier at all. Due to the ECP, each trace must be governed by a lexical head, or extraction must be local (short distance). Long extraction in (15)–(16) is correctly ruled out by the ECP, because the relevant traces are not governed by any lexical head.

The current status of the ECP becomes somewhat controversial, partially because of subsequent attempts to eliminate the notion of (proper) government, building on various theory-internal considerations. However, the elimination of proper government has, as yet, left a few questions unanswered (e.g., the difference between argument extraction and adjunct extraction out of an island, etc.). Therefore, an alternative characterization of the ECP effect is left for future research.

Economy-Based Accounts: Minimality and Last Resort

The fourth category of locality constraints grows out of the research guided by the so-called Minimalist Program (Chomsky, 1995), which aims to achieve a minimal formulation of grammatical theory. We can approach this goal either by reducing the set of theoretical apparatuses to a bare minimum, or by attributing them to principles of 'least effort' or minimal computation that are more deeply grounded in laws of nature, hence not adding to the burden of Universal Grammar.

One such attempt was Rizzi's (1990) theory of Relativized Minimality, according to which each movement operation of type X (A-, A′-, or head-movement) must always land at the closest potential landing site of the same type X. For example, (17b) and (18c) are ruled out as A-movement and

head-movement skipping an intermediate A-position and head-position, respectively.

(17) a. It seems that *Juma*$_i$ is likely [t_i to win].

b. **Juma*$_i$ seems that it is likely [t_i to win].

(18) a. They could have left.

b. *Could*$_i$ they t_i have left?

c. **Have*$_i$ they could t_i left?

Cases of the WIC (15) are also ruled out as A′-movement violating Relativized Minimality. In Chomsky (1995), minimality is directly incorporated into the definition of Attract F, a reformulation of Move α that seeks and attracts a category with the matching feature F that is closest to the relevant landing site (for example, *wh*-movement of *what* into the specifier of CP = [C *you* Infl *see what*] is reformulated as an instance of Attract F, initiated by C's Q(uestion)-feature attracting the matching Q-feature of *what*). Chomsky (2000) proposes the mechanism of Agree as a further reformulation of Attract F, which just relates an item with a (typically uninterpretable) feature F (the 'probe') to the closest item with a matching F (the 'goal').

Another type of economy condition is the principle of Last Resort, which restricts the otherwise unbounded application of Move α/Merge to only those which are minimally necessary for the derivation to converge (i.e., receive appropriate interpretation) at LF and PF. For example, under the assumption that A-movement is generally driven by the need of an NP to receive abstract Case (Nominative, Accusative, Genitive, etc., which are overtly manifested in, e.g., English pronominal systems, as in *he*, *him*, *his*, etc.) assigned to a relevant A-position (subject, object, possessor, etc.), A-movement from one case position to another case position is superfluous and thus prohibited by Last Resort.

(19) a. It seems that John got a Nobel prize last week.

b. **John*$_i$ seems that t_i got a Nobel prize last week.

c. **A Nobel prize*$_i$ seems that John got t_i last week.

Further considerations are attributed to the general principle of economy along the line with the Minimalist Program. For example, it has been argued that the cyclic derivation by phase also has an important function of periodically reducing memory loads of the active workspace, contributing to computational efficiency (Chomsky, 2000 *et seq*). Another economy condition is the principle of Full Interpretation (Chomsky, 1986a, 1995, 2000, 2004; see also Narita, 2014 for discussion), which requires that every element of PF and LF must receive an appropriate interpretation, forcing all non-interpretable elements (e.g., agreement features) to get checked off and deleted in the course of derivation.

Covert Movement

We have seen a number of cases where movement is overt, with phonetically visible effects, while it has also been widely assumed that certain elements may move covertly as derivations enter LF, producing no phonetic effect. It was specifically assumed in the earlier Government-and-Binding framework that movement may be overt if it occurs before SS, or it may be covert if it occurs in the so-called LF-component (the mapping from SS to LF). Sentences containing quantifiers such as *everyone*, *some student*, *most people* exemplify a movement operation of the relevant sort, referred to as Quantifier Raising (QR). Chomsky (1976) argued that quantifiers are located covertly on the (left) periphery of the clause containing them, binding a variable in their surface position. Thus the surface sentence *John hates every politician* has the predicate-calculus style of representation *For every x*, *x a politician*, *John hates x*. May (1977) suggested that this representation may be obtained by an instance of Move α that raises the quantifier leftward, in a style reminiscent of 'quantifier lowering' rules proposed by generative semanticists in the early 1970s. Important arguments include generalizations concerning the possibilities of interpreting pronouns as 'bound variables' (Higginbotham, 1980).

Another sort of covert movement is that of *wh*-phrases in languages in which they typically occur in their 'original' positions. Unlike English-type languages, Chinese (and many other languages) leave their question words '*in situ*' when forming *wh*-questions. Thus *What did you buy*? in English is simply *ni mai-le shenme* 'you bought what' in (Mandarin) Chinese. Note that the Chinese sentence (20) is ambiguous between a direct and indirect question reading, corresponding to two distinct forms in English (21):

(20) ni Jide Zhangsan mai-le shenme

you remember Zhangsan bought what

(21) a. *What*$_i$ did you remember that John bought t_i? (direct question)

b. You remembered *what*$_i$ John bought t_i. (indirect question)

Despite the overt differences, Huang (1982) argued that the two languages (and all languages) have essentially the same LF representations. In particular, although *wh*-phrases do not move overtly in Chinese, they do so covertly in LF. The ambiguity of (20) follows as a result of the fact that *shenme* 'what' may be moved to the subordinate clause below *jide* 'remember' or to the main clause, deriving LF representations not unlike (21a,b). In addition to capturing certain crosslinguistic generalizations, this hypothesis is supported by the fact that interpretation of *in situ wh*-questions is subject to some restrictions that govern overt movement, e.g., the ECP.

As an instance of Move α, covert movement was not limited to A′-movement like QR or *wh*-movement. Given the *wh*-movement parameter (some languages move *wh*-phrases overtly, others do it in LF), proposals exist in the current literature that both A-movement (e.g., object shift) and head-movement (e.g., V-to-I or I-to-C raising) may occur overtly in some languages but covertly in others. However, the status of the covert LF-component is controversial in the current research under the Minimalist

Program, partially because intermediate levels of representations such as DS and SS got eliminated, and also because the post-SS instances of Move α were not obviously reducible to bottom-up (hence strictly cyclic) applications of Internal Merge. Therefore, a number of researchers currently investigate a reductive approach to covert movement, where the effect of covert LF-movement is relegated either to instances of Agree (feature-matching) without movement (Chomsky, 2000), or to PF deletion of higher (instead of lower) copies of Internal Merge (e.g., by postponing applications of Internal Merge until after Spell-Out; see Nissenbaum, 2000).

Conclusion

The study of movement in syntactic theory has been proven to be a productive probe into the inner workings of the human language faculty. Many discoveries were made and questions addressed since the very beginning of generative grammar: the typology of movement operations (A-, A′-, and head-movement), various constraints on extraction from and of certain structures, the parametric existence of covert movement and its possible reformulations, and various considerations on minimality and computational economy. In current Minimalist inquiries, ever more emphasis is put to the role of Movement/Internal Merge, with new consequences that will continue to intrigue future researchers.

Abstract

Social movements are important agents of social, political, and cultural change, dating back from the present to at least the far-reaching empires of the Greco-Roman world and the various rebellions and religious movements spawned during that era. This article sketches a general overview of social movements, accenting their role as carriers of social change, providing a working conceptualization, elaborating the varieties or types of social movements, and identifying the focal issues and questions that animate most research on social movements.

Social movements and the associated phenomena they often organize and sponsor, ranging from peaceful protest demonstrations to acts of political violence, from pamphleteering to revolution, and from mass vigils memorializing deceased constituents to boisterous gatherings clamoring for retribution, are collective actions through which aggrieved collectivities give voice publicly to various grievances and press relevant authorities to attend to the associated claims and/or demands. The grievances generally range from political and religious oppression to socioeconomic inequalities to procedural and/or rights-based inequalities to all kinds of lifestyle concerns and perceived social and environmental harms. Although there are other institutionalized forums in which collectivities can express their grievances and concerns, particularly in democratic societies, social movements have functioned as an important vehicle for articulating and pressing an aggrieved collectivity's interests and claims for much of human history. Certainly many of the most significant events and changes throughout the course of human history – such as the rise and spread of Christianity and Islam, the Reformation, and the French, American, Russian, and Chinese Communist Revolutions, for example – cannot be fully understood apart from the operation and influence of social movements. Similarly, many of the world's most influential and famous figures – such as Jesus Christ, the Apostle Paul, Muhammad, Martin Luther, Valdimir Lenin, Mohandas Gandhi, Mao Se Tung, Martin Luther King Jr., and Nelsen Mandela – gained their celebrity and influence, in part, from the movements with which they were associated and/or lead. More generally, one would be hard pressed to identify a drastic shift in any group's social standing, historical or contemporary, that occurred without some kind of organized contention precipitating it. And today, it is difficult to name a contested social issue throughout much of the world with which a social movement is not associated on at least one side of the issue. Whatever the issue – abortion, animal rights, civil rights, human rights, democratization, climate change, gender equality, gun control, immigration, labor and unions, nuclear weapons, religious freedom, war, water conservation and control, and world poverty – one typically finds one or more associated social movements. Whether we live in a 'movement society' or world, as some scholars have suggested (Meyer and Tarrow, 1998), there is little question but that social movements are important social phenomena and that our understanding of the social world, both past and present, is partly contingent on our understanding of social movements and the activities and events with which they are associated.

Conceptualization

As with many concepts in the social sciences, there continues to be little consensus as to how best to define social movements. Some scholars emphasize the strategic, rational, and organized character of social movements (McCarthy and Zald, 1977); others focus on the networked and coalitional character of movements (Della Porta and Diani, 2006); some accent the ideological element of movements (Zald, 2000); still others emphasize the 'manifestly political' character of movements as a form of contentious politics with one or more governments as a claimant or target of claims (McAdam et al., 2001); and some scholars argue for a more inclusive and elastic conceptualization, one that conceives of movements broadly as collective challenges to institutional, organizational, and cultural domains other than just the state or the polity (Snow, 2004; Snow and Soule, 2010). However, one does not have to choose one emphasis or focus over another so long as it is recognized that each conceptualization accents a particular dimension or aspect of social movements. Thus, whatever dimensions of movements a scholar might accent, it can be argued that all social movements share a number of characteristics that together define the phenomenon. First, all movements are change oriented in the sense that they seek or oppose change, although there can be considerable variation in the level and degree of change sought; second, movements are, as a consequence of this change orientation, challengers to or defenders of existing institutional structures or systems of authority, be they political, religious, corporate, educational, or cultural; third, movements are collective rather than individual enterprises; fourth, they act outside of existing institutional or organizational arrangements, although in varying degrees with some movements employing only extrainstitutional tactics and others working within institutional channels while also engaging in some extrainstitutional collective action; fifth, they operate with some degree of organization, ranging from a single social movement organization (SMO) to a network or

coalition of movement organizations that may vary in the degree to which they are tightly or loosely coupled; and sixth, social movements typically display some degree of temporal continuity – they are relatively episodic but rarely fly-by-night fads that are here today and gone tomorrow (see Snow and Soule, 2010).

Varieties of Movements

Although all social movements can be defined in part by the above characteristics, they can also be differentiated in terms of these characteristics. It is worthwhile to consider that even so-called reactionary or conservative movements opposing change must advance their own challenges to authority in responding to real or perceived currents of social change. Therefore, the most common axis of such differentiation concerns the degree or amount of change pursued, which makes sense since the promotion of or resistance to change is the raison de' etra of virtually all social movements. The most basic distinction in this regard is between *reform* and *revolutionary movements*. A more subtle distinction is provided by Smelser's (1962) differentiation between norm-oriented and value-oriented movements. *Norm-oriented movements* are said to seek relatively limited but specific system changes, mainly with respect to rights and rules of access and participation in the various societal institutions. Examples might include movements that have sought to change labor laws, decriminalize marijuana, expand or restrict immigrant rights, and criminalize or decriminalize abortion. *Value-oriented movements*, in contrast, seek more fundamental changes in cultural values and institutional structures and practices, as with movements that seek to redefine the fundamental rights and privileges of personhood and citizenship, like the Gandhi-led Indian Independence Movement and the African-American Civil Rights Movement, or those that have sought to recalibrate the very structure of political governance and association and the values on which they are based, as with the French and American revolutions.

Wallis (1984) provided a similar typology with his distinction between world-rejecting and world-affirming movements. Although developed to capture differences mainly among religious movements, this dichotomy parallels the norm- and value-oriented distinctions. The world-rejecting movement, like the value-oriented movement, condemns the dominant social order, including both its values and institutional arrangements, as in the case of Jim Jones' Peoples Temple that culminated in the mass suicide of its members. World-rejecting movements are not confined to the realm of new religious movements; both the peaceful separatist anarcho-primitivists within the Green Anarchism movement and the anti-industrial agenda of the 'Unabomber' Ted Kaczynski are characterized by their rejection of the existing social order. The world-affirming movement, like the norm-oriented movement, is less contemptuous of the prevailing religious or social order and thus seeks more selective changes in specific segments of that enveloping order, as with organizations such as the People for the Ethical Treatment of Animals or the variety of organizations within the predominately Christian anti-abortion movement. While world-affirming movements may hold forward-looking and/or radical views, their objectives still operate on the assumption that society is redeemable and equipped with the tools for change.

By focusing on the amount or degree of change sought, the above schemes provide one basis for differentiating among movements, but they are incomplete because they neglect the fact that change can have a different focus or occur at different levels. This oversight was addressed by the anthropologist Aberle (1966) in his research on the Peyote religion among the Navaho Indians in the southwest region of the United States. He differentiated among movements based on both the degree of change and the locus or level of change sought, directing attention to the target of change that can vary from the individual level to some aspect of the broader structure. Based on the cross-classification of these two dimensions, Aberle derived four generic types of movements. *Alterative movements* seek partial change in individuals as in the case of the therapeutic and self-help movements that proliferated in the United States in the 1970s and 1980s. *Redemptive movements* seek a more complete, or total rather than partial, change among individuals, which was the objective of various religious movements that flowered in the 1970s, such as the Hare Krishna and Unification Church (Moonies) movements. Characteristics of redemptive movements can also be observed in the strictures of more recent lifestyle-centered movements, such as the vehement rejection of all intoxicants and so-called poisons by adherents of the straight-edge lifestyle. *Reformative movements* seek limited but focused changes in the social system like the normative and world-affirming movements noted above; and *transformative movements*, are akin to value-oriented and revolutionary movements.

An alternative approach to differentiating social movements takes a more historical approach, contrasting movements clustered in different historical areas. Differences in the amount and locus of change sought are not ignored, but the crucial criterion is the affinity between certain historical trends or changes and movement goals and/or strategies and tactics. Perhaps the earliest and most cogent illustration of this approach is found in Mannheim's *Utopia and Ideology* (1946), wherein he identifies four major waves of movements in so-called modern times: *chiliastic movements* expressed in some religious movements and peasant revolts; *liberal humanitarian movements* associated most dramatically with the French and American revolutions; *conservative movements* expressed must fully in fascism and Nazism; and *socialist movements* associated mainly with international communism but also influencing labor movements in the United States, Europe, and elsewhere. Extending Mannheim's historical approach, Turner (1969: pp. 391–395) argued that "major eras in history have differed in the dominant sense of injustice which underlay the major movements of the time and dictated the main direction of social change," contending that both the liberal humanitarian and socialist conceptions of injustice have been exhausted and that "a new revision is in the making." Foreshadowing aspects of new social movement theory, Turner argued that the emerging change preference concerned the yearning for a satisfactory sense of personal worth, dignity, and identity. New social movement theory emerged in the 1980s in Europe to analyze the so-called *new social movements* that began to surface in the 1960s and which were seen as being different

from the older, materially based working-class and labor movements associated initially with Marxism. In contrast, the new social movements – such as the environmental movement, human rights movement, and gay, lesbian, bisexual, and transgender movement – are driven by concerns with procedural rights and various lifestyle issues (Buechler, 2011: pp. 157–173; Kriesi et al., 1995; Larana et al., 1994).

Also acknowledging the link between varieties of movements and historical change, Tilly (1993, 2006) advanced the concept of *repertoires of contention*, identifying particular strategies and tactics for political claims making associated with particular historical and political periods. In particular, Tilly distinguished between an older repertoire associated with the eighteenth century and a newer repertoire associated with the nineteenth century and the development of the nation-state. Tarrow summarizes the distinction as such: The newer repertoire "was cosmopolitan rather than parochial; autonomous rather than dependent on inherited rituals or occasions; and modular rather than particular" (1998: p. 37). "Unlike the older forms, which expressed people's immediate grievances directly against antagonists, the newer repertoire … could be used by a variety of social actors on behalf of a number of different claims and serve as a bridge among them to strengthen their hand and reflect broader and more proactive demands" (Tarrow, 1998: pp. 66–67). However, these repertoires may not simply pass out of existence with the arrival of a new era of contention. This ongoing theme of historical variation in movement characteristics is seen even more recently in the work of scholars who have suggested that the rise of the Internet communication and virtual outlets for activism has prompted the emergence of a new 'digital' repertoire of contention (Earl and Kimport, 2011).

Following Tilly and Tarrow, much work on social movements has focused on state-centered social movements. However, it is important to note that movements are not solely engaged with political institutions but may rather emerge from a host of other institutional interactions including those with religious institutions and other centers of authorities. Young's research (2006), for example, shows that the first sustained national movements in the United States arose in the 1820s and 1830s in response to religious forces, rather than political institutions, calling Americans to bear witness against the sins of intemperance, slavery, and other moral wrongs. These nonstate institutional engagements have persisted throughout history and generated no lack of movements for their own part, as can be seen in the institutional protest seen within the Catholic Church at various stages of its history and the ongoing struggles of women within various institutional sectors (Katzenstein, 1999).

A final basis for differentiating among movements relates to strategic and/or tactical differences. Perhaps the foremost example is the distinction between violent and nonviolent movements. Although the use of violence may occur intermittently in a movement's career, some movements are sometimes defined in part by their strategic use of violence, as with terrorist movements at both poles of the political spectrum, or nonviolence, as with the US Civil Rights Movement and the pacifist Plowshares nuclear disarmament movement (Nepstad, 2008). Strategic or tactical actions are also pivotal in McAdam et al. (2001) distinction between *constrained contention* and *transgressive contention*. In the case of the former, "well established means of claims making are employed" (p. 7), which is to say that they are institutionalized or routinized; whereas in the case of transgressive contention, some parties embroiled in the contention 'employ innovative collective action' – that is, the claims or means are "either unprecedented or forbidden within the regime in question" (p. 8). The selection of tactics and formation of strategy is neither solely a response to a movement's environment nor dictated wholesale by a movement's ideology but rather emerges from a dynamic interplay between multiple factors. Although a movement's tactics will generally accord with its ideological underpinnings, as is the case of the nonviolent sabotage of nuclear missiles undertaken by the pacifist Plowshares movement, SMOs have proven oftentimes to be highly adaptable and innovative in their strategies. Moreover, a movement cannot be characterized as violent or nonviolent, or constrained vs transgressive, in its entirety based upon tactics observed in a sample of protest events alone, as movements will often deploy a broad spectrum of tactics within its various flanks.

Clearly there are a number of alternative ways of differentiating and typologizing social movements. Although much of the extant literature on social movements has focused on left and progressive movements, and/or movements in predominately Western democratic settings, scholars are increasingly attentive to movements on right, far right, and outside of the field of conventional left-wing movements for which earlier conceptualizations may be insufficient (Blee and Creasap, 2010; Hirsch-Hoffer and Mudde, 2013; McVeigh, 2009). What is important is to be cognizant of the different axis of differentiation and to not assume that the conditions that account for the emergence and operation of movements of one type necessarily apply to all types of movements. As well, it is important to keep in mind that all of these theoretical typologies of movements are ideal types of sorts and therefore are likely to be rare, given the significant permeability between the various categories.

Focal Analytic Issues and Questions

As the study of social movements has evolved to the present, most inquires and research are guided by a variant of one or more sets of four focal questions. First, there is the long-standing concern with conditions underlying the *emergence* of social movements. Here there are two associated questions: Since movement adherents are generally stirred to action by a combination of grievances and a sense of efficacy, what are the processes and mechanisms that account for the generation of these mobilizing sentiments? And, since the occurrence of social movements is nested temporally and spatially rather than randomly distributed across time and place (Koopmans, 2004; Tarrow, 1998), what specifically are the sets of contextual conditions that facilitate or constrain the emergence and flourishing of social movements? Early lineages of social movement research, organized under the broader heading of collective behavior, emphasize the role of strains, relative deprivation or structural grievances as generative of

contentious collective action (see Buechler, 2011: pp. 9–106). Although the rise of the political opportunity perspective (see McAdam et al., 1996) has consequently shifted a great deal of scholarly attention to the role of contextual favorability within a movement's political setting, the importance of grievance-generating conditions in movement emergence cannot be overlooked.

The second orienting question concerns the issue of micro-mobilization or *recruitment and participation processes*. Here there is a subset of questions as well: What is the character of movement participation? What are the different ways of participating? And what are the determinants of who participates in social movement activities, and why? Why do only certain individuals come to participate in movement activity while other similarly situated individuals remain on the sidelines? Among the many conditions necessary for participation in a range of movement activities, a rare consensus emerges that one of the single most critical precipitating condition is simply being asked (Schussman and Soule, 2005). Within the wealth of studies attending to this question, scholars have uncovered various permutations of conditions conducive to participation, ranging from the resonance of a movement's frames with a target constituency (Benford and Snow, 2000), affective networks, and relationships as powerful recruitment mechanisms (Diani, 2004) to the spatial ecology of a setting, as observed in the large-scale mobilization of university students in the Tiananmen pro-democracy protests of 1989 (Zhao, 1998).

The third focal question concerns the *dynamics* of social movements. What happens once a movement has surfaced and it is, so to speak, up and running? More concretely, how are social movements organized and led, and how do they go about the business of strategically pressing their claims and dealing with the various relevant actors within their field of operation? What or who are the relevant actors that constitute the movement field of action, and what are their relationships? And what are the various mechanisms and processes associated with the operation and functioning of social movements? Such concerns strike at a broad range of possible processes and conditions within which social movements are enmeshed, necessitating refinement when posing such analytical questions. Generally, scholars of social movements have directed their emphasis variously upon internal dynamics, such as the importance of leadership (Morris and Staggenborg, 2004), mechanisms to sustain participation and persistence over time (Taylor, 1989; Nepstad, 2008), organizational form (Clemens and Minkoff, 2004), and finally SMO resources, as evidenced by the highly generative theory of resource mobilization (McCarthy and Zald, 1977). Among the many dynamics studied, of particularly recent attention has been the study of tactics and strategies. Just as movement organizations may occupy a range of niches within a given social setting, the tactics they deploy will range from highly institutionalized (constrained) to the most transgressive or extrainstitutional. Moreover, movements do not simply settle upon one approach and maintain it for the duration of its activities. As discussed earlier, tactical selection and strategy formation is subject to a host of both internal and external processes, operating at multiple levels within the movement.

The fourth general, focal issue concerns what many scholars and social movement activists consider as the bottom-line question: What difference do movements make, and for whom and in what ways? Do social movements play an important role in challenging authorities and generating impending social change? Are there other functions that they perform? What, in short, are the *consequences or outcomes* of social movements? A number of scholars characterize movements as being both effective and important actors that can be instrumental to lasting social change. Others address movements more cautiously and temper conclusions as to their effects, viewing them as generally ineffective in affecting long-term change or that their influence is predominately a function of already conducive political and social climates as well as favorable political administrations. More recent conceptualizations have expounded upon narrower definitions of movement success and instead focused on a range of outcomes, such as long-time policy feedbacks, cultural consequences, and biographical consequences for the individual participant (Amenta et al., 2010; Giugni et al., 1999; Snow et al., 2013).

Answers to these questions understandably draw on a range of overlapping perspectives and processes, including political process theory, resource mobilization theory, ecological and spatial perspectives, framing processes and theory, cultural perspectives, social psychology, as well as other perspectives and points of view.

Abstract

H.J. Muller, founder of the field of radiation genetics, won the Nobel Prize in Medicine and Physiology in 1946 for having demonstrated that he could induce mutations with X-rays in fruit flies. Muller was also a contributor to classical genetics in T.H. Morgan's 'Fly Lab.' Unusual for his generation, he left the ivory tower and participated in the social implications of science. He denounced the American eugenics movement as elitist, biased, racist, and sexist but advocated a positive eugenics based on talent, intelligence, leadership, and empathy, which he hoped would be carried out in states favoring social equality. He was sympathetic to the Bolshevik Revolution and edited an underground procommunist newspaper, *the Spark*. He left the United States for Berlin, then Leningrad and Moscow, then fled the USSR during the Lysenko controversy and fought in the Spanish Civil War. He worked at Edinburgh until World War II broke out and then returned to the United States, finding a permanent home in Indiana University. Muller considered himself a reductionist in science, a socialist in political outlook, a critic of totalitarianism in all its forms, and a champion of radiation protection for the public.

Hermann Joseph Muller was born in New York City on 21 December 1890 and he died in Indianapolis, Indiana, on 5 April 1967. He is best known as an American geneticist, the founder of the field of radiation genetics, for which he received the Nobel Prize in Medicine or Physiology in 1946. He was also a controversial critic of the way science is abused by society and he was both a critic and proponent of eugenics (Carlson, 1982). Muller's paternal ancestors came to the United States after the 1848 Revolution. They had lived in the Coblenz area of the Rhine and were Catholics. Muller's father became a Unitarian and Muller abandoned all religions for secular humanism and considered himself an atheist from his high school years on. Muller grew up in New York City and attended Morris High School in the Bronx. His father was co-owner of a metal art shop that produced frames and plaques. From those first Muller settlers in the United States came first cousins Alfred Kroeber, a noted anthropologist and Herbert J. Muller, an English critic known for his best-seller, *The Uses of the Past*. Muller attributed his early interest in evolution and socialism to his father, who died when young Muller was 10 years old. Muller's maternal side, the Lyons family, was of mixed Anglican and Jewish ancestry before they emigrated from England to the United States. Muller excelled in high school and was awarded a scholarship to attend Columbia University.

Founding the Field of Radiation Genetics

The field of radiation genetics emerged after 1927 when Muller published his first articles on the artificial induction of mutations by X-rays in fruit flies (Muller, 1927). Within a few years, geneticists around the world were using X-rays to induce mutations for both basic genetic research and for applied uses, especially new mutations of commercial importance in agriculture. One of the most significant applications was the production and selection for increased yield of penicillin from the fungus *Penicillium* in the later 1940s. Although Muller did virtually all his research using fruit flies, he made applications of that knowledge to working out the major features of classical genetics and to human genetics, evolution, and fundamental findings such as the mechanism that caused radiation sickness among those exposed to high doses of radiation at Hiroshima and Nagasaki from atomic bomb radiation release.

Muller found the courses of Edmund Beecher Wilson particularly influential in introducing him to the chromosome theory of heredity and the relatively new field of Mendelian genetics. He established a biology club with fellow undergraduates Alfred Henry Sturtevant and Calvin Blackman Bridges. They joined Thomas Hunt Morgan's laboratory as it shifted from embryology to genetics using fruit flies. The 'Fly Lab' as Sturtevant called it, established many of the basic tenets of classical genetics, including the finding of X-linked inheritance, the discovery of crossing over among genes on a shared pair of chromosomes, the occasional gain or loss of a chromosome through nondisjunction, and, of particular interest to Muller, the relation of genes to character expression (Carlson, 2007). Muller completed his PhD in 1916 and took a job in Julian Huxley's new Department of Biology at Rice University in Texas. He chaired the Department when Huxley returned to Great Britain to serve in World War I. Huxley and Muller remained life-long friends, sharing an interest in positive eugenics, the differential breeding that favored intelligence, good health, qualities of leadership, and an altruistic empathetic personality.

From 1916 to 1926, Muller developed a theoretical genetics based on the findings of the Fly Lab. He noted that genetic changes involved different processes, some associated with the number and integrity of the chromosomes and some with the individual gene. Muller argued that "variation due to change in the individual gene" was the primary mechanism of Darwinian evolution by natural selection (Muller, 1922). He also argued that the gene was the basis of life because it was a molecule capable of copying itself and its errors, making evolution possible (Muller, 1936a). His focus on the individual gene led him to study the time of origin of mutations and how they were expressed on first appearance and how frequently they were transmitted or arose by spontaneous mutation. This in turn led him to believe the induction of mutations was possible. He began a series of experiments, one using temperature, and the other using X-rays, to show mutations could be artificially induced. What distinguished Muller's success from earlier failures by Morgan and others was his design of genetic stocks

that would detect mutations objectively and quantitatively. In 1927, he published his findings in *Science* and presented his data in detail at the International Congress of Genetics in Berlin.

Muller's Contributions to Classical Genetics and Evolution

Muller's first contribution to evolutionary theory (1918–21) was his study of two mutations, beaded and truncate wings (Muller, 1918; Altenburg and Muller, 1920). In each case, he showed the existence of a chief gene, modifier genes that either boosted or diminished the expression of the wing trait, and environmental factors, such as temperature on the expression. Muller isolated the modifier genes and mapped them and he could combine different modifiers with the chief gene and predict the number of quantitative distributions of wing deformity based on these components. He used this as strong evidence favoring Darwin's thesis of natural selection. His second major contribution was the 'gene doctrine.' In 1936, he studied bar eyes in fruit flies and showed that it was associated with a duplicated tandem segment that arose from unequal crossing over. Muller argued that chromosome length and number could be interpreted through this mechanism and that all genes arise from preexisting genes. Muller believed the gene was the basis of life because it was a molecule that could copy its errors, a feature he believed essential for life to evolve. Muller's third major contribution to evolution in 1932 was his identification of genetic recombination as the basis for the emergence of sex (Muller, 1932). His fourth contribution is called Muller's ratchet. Muller argued as early as 1918 that if a chromosome is prevented from recombination through crossing over, it will accumulate mutations and deletions of its genes. He used this to explain the evolution of the Y chromosome and why it is virtually void of genes except for those associated with sex determination or spermatogenesis.

Muller's Social Views of Genetics: The Eugenics Movement

Muller was a socialist from his high school days. He shifted to bolshevism after the Soviet Union was established. In this role, he favored the social reforms advocated in magazines like *The Masses*. He felt capitalism was unjust and neglected or opposed equal opportunities for women, minorities, and the laboring classes. At the same time in the United States, there was a robust eugenics movement founded by a committee of the American Breeder's Association, chaired by David Starr Jordan and backed by Alexander Graham Bell. They established a eugenics station at Cold Spring Harbor with Charles Davenport as its director. The eugenics outlook favored by this center was called negative eugenics because it stressed the culling of undesirable traits from the American population. They used a multiple approach of institutionalizing the mentally retarded and insane; they backed state compulsory sterilization laws especially by vasectomy and tubal ligation; and they favored marriage laws that restricted who could marry based on considerations of eugenics and race. They also favored restrictive immigration laws, especially against those from southern and central Europe (especially Jews, Poles, Slavs, Serbs, Italians, and those from Balkan nations) who were the majority of immigrants coming to the United States between the 1890s and World War I (Carlson, 2001).

Muller opposed this negative eugenics movement and denounced it at the Third International Congress of Eugenics in 1932, which was held at the American Museum of Natural History. In his paper, 'The dominance of economics over eugenics' Muller accused the movement of being racist, sexist, and elitist, and showed how its basic assumptions were based on wishful thinking and bias rather than science. He felt that eugenics could only be put into practice, if the social conditions were equally favorable to all children, not just those favored by the capitalist values of the Eugenics Record Office. That utopian social outlook he claimed existed only in the USSR. Back at Texas, he was having difficulties with the FBI because he helped edit and distribute an underground unsigned student newspaper, *The Spark*, named for Lenin's *Iskra*. Some trustees wanted Muller investigated and tried by the academic senate for unprofessional behavior. *The Spark* condemned both American society and the state of Texas for its racism against African-Americans, for its failure to provide jobs for graduates because of the Depression (Hoover was still President), and for its hostility to the teaching of evolution in public schools.

Muller left the United States in 1932 and headed to Berlin on a Guggenheim Fellowship. Hitler came to power soon after and Muller was again forced to relocate, this time to the USSR where the head of Soviet agricultural science, N.I. Vavilov, invited him to be a guest investigator. While Muller denounced race hygiene in Germany and other countries in Europe, he promoted his enthusiasm for positive eugenics in a book, *Out of the Night*. Muller's eugenic idealism and socialism are reflected in this work (Muller, 1936a). He believed sperm banks could be used to provide those choosing a eugenic option for children and that the values associated with that choice should be high intelligence, unique valued talents, good health, mental stability, a gregarious personality, and a compassion or empathy for others. He shunned eugenic selection based on notoriety in popular culture and he felt sterilization and restrictive immigration were bad policies based chiefly on discrimination.

Muller's Social Views: The Defense of Science in the USSR

Like many left-wing Americans in the 1920s and early 1930s, Muller felt that the USSR was on the right track to establishing a democratic and just society. In the USSR, there was an English language newspaper (published in Moscow) for those who emigrated there from the United States and for those who were deported by the United States for subversive activity, especially organizing labor unions, condemning racism, or being members in anarchist or communist organizations. Muller established a laboratory first in Leningrad and then in Moscow with numerous graduate students, including two he brought with him from Texas. Muller devoted much of his research to cytogenetics, the study of genes in relation to chromosome changes, and it was here that his gene doctrine emerged. But in

1936, a new movement began in the USSR at the agricultural field station in Odessa. It was led by Trofim D. Lysenko and he called his movement Michurinism. It would be called Lysenkoism in the West. Lysenko was a plant physiologist and practical breeder who believed that he could shatter and retrain the heredity of cereal plants and transform them. His initial claim was that he could shift winter wheat into spring wheat by soaking the grains in ice water. The USSR had wretched weather for its crops because its collective farms were at high latitude and the growing season was short. This led to frequent crop failures. Lysenko promised a revolution in agriculture with his techniques. Soon, he had a sizable following and began challenging classical genetics as slow, pessimistic in its assessments, and reflective of suspect origins from a Moravian monk (Gregor Mendel) whose ideas were central to Nazi race hygiene. Muller found himself spending more of his time defending Vavilov and classical genetics than he desired. A showdown took place in December 1936 in which 3000 participants appeared in Moscow for a debate between Lysenkoists and Vavilov's classical geneticists. When Muller gave his talk he denounced Lysenko as a charlatan, with Michurinism indistinguishable in his views from pseudosciences like alchemy, numerology, and medical quackery or even shamanism. This created a storm of protest from the Lysenkoists and Vavilov told Muller he had better find a way to leave gracefully. Muller did so by joining the International Brigade to fight in the Spanish Civil War. He served in Norman Bethune's blood unit and did experiments to see if cadaver blood from freshly killed soldiers could be used for transfusions. After the siege of Madrid, he was forced to flee again and this time Huxley found him a job in Edinburgh at the Institute for Animal Genetics.

The outbreak of war in 1939 led to a lull in the debate between Lysenko and his detractors. After the war it erupted again in 1948 when Muller denounced Lysenkoism at the International Congress of Genetics in Stockholm. In Moscow, a second showdown debate was scheduled and Lysenko announced that his views were officially endorsed by the Central Committee of the Communist Party. One by one those who were engaged in classical generics studies recanted and pledged allegiance to Michurinism. Until the mid-1960s Lysenkoism became the official doctrine and practice of genetics in the USSR and the Eastern Bloc. It collapsed because Lysenko could not deliver on his promises and those farmers who tried to use Lysenko's techniques complained to their representatives that it did not work. After the collapse of the Soviet Union, Lysenko was revealed as a self-deceived fraud, who bullied farmers into falsifying documents that his techniques worked, by accusing them of sabotage if they failed to do so (Medvedev, 1969).

Muller Fails to Establish a Positive Eugenics Program

In 1957, Muller revived positive eugenics. He believed enough years had elapsed since the war ended and a revival of race hygiene or a movement like the American eugenics movement that Davenport had promoted was not likely to recur. Instead, he proposed what he called 'germinal choice.' It would not be the state or an institution tied to a genetic organization that determined the use of sperm in sperm banks but the users themselves. By allowing couples access to the records of accomplishments and medical records of the donors to sperm banks, Muller believed users would be as serious in their choices as they would for any major decision they were making about their lives, like buying a home, moving to a new location, or choosing a career. Muller was criticized for reviving eugenics by many of his colleagues and by the press, which carried stories of his speeches. They saw all eugenics as doomed to exploitation and leading to bias. Muller argued that our 'load of mutations' was increasing because natural selection was minimized as civilization and modern medicine replaced the ruthlessness of life some 10 000 or more years ago (Muller, 1950). The germ theory shifted infant mortality from 50% in the mid-nineteenth century to less than 1% in the mid-twentieth century in industrialized countries. The best way to circumvent this accumulation was by selective breeding based, he believed, on germinal choice. Muller found only one group interested in applying germinal choice. It was a private group in California calling itself the Foundation for Germinal Choice. Muller visited the sponsors and came away disillusioned because they were only interested in high intelligence and their criterion was the College Entrance Examination Board scores (a top score of 800 on the verbal or mathematical section). Muller felt the people backing this 'sperm bank for geniuses' shared the values of Davenport and his supporters. He forbade use of his name as an endorsement and told his wife that he would rather have no eugenics program than a bad one.

Muller's Concern for Radiation Protection

While many criticized Muller for returning to eugenics in the 1950s, they held him in esteem for raising concern about radiation protection (Muller, 1952). Muller first took an interest in this issue in 1927 when he induced mutations with X-rays in fruit flies. By the 1930s, he and those who were inspired by his work around the world had found that the induction of mutations was roughly linear. Thus a dose of 500 R would give one fourth of the mutations obtained at a dose of 2000 R. A second finding was that when Muller devised a genetic test to detect translocations (an exchange of pieces of nonhomologous chromosomes), they did not obey a linearity of dose to occurrence. Instead they rose exponentially to about the 3/2 power. From these findings Muller concluded that relatively low doses would be of concern for the gene mutations they produced but not for the chromosomal rearrangements they produced because at low doses these were virtually nonexistent. But gene mutations, if extrapolated to lower doses would be cumulative and Muller believed that those exposed chronically to low doses, like physicians, dentists, industrial workers using X-rays to examine for stress fractures in metal, shoe salesmen (in those days shoe size was done by fluoroscope in shoe stores), or chiropractors (who routinely examined spines for displacements) should protect themselves with lead shielding or move away from the radiation source (the dose diminishes rapidly with distance). Many dentists used their fingers to hold the film in the patient's mouth and many physicians stood unshielded by the fluoroscope when examining the patient's internal organs. Muller criticized those who tried to induce ovulation in infertile

women by X-raying their pituitary gland and their ovaries with relatively high doses (about 200 R where a typical chest X-ray then was about 0.1 R).

It was not until 1946 that the health professions began to listen to Muller. They realized the harm from radiation exposure at high doses to a population from descriptions of radiation sickness in Hiroshima and Nagasaki in 1945. After Muller was awarded a Nobel Prize for his work, he was sought as a speaker at universities and by medical groups. He argued that the linearity of dose to mutation production was based on both extrapolation and from studies of attenuated doses compared to acute doses. S.P. Ray-Chaudhuri did experiments while Muller was in Edinburgh that compared 400 R given in 30 min to fruit fly males and to a population of male flies that was exposed to almost a month of radiation that cumulatively equaled 400 R (Ray-Chaudhuri, 1944). This meant that in any 1 min they were receiving less than a chest X-ray's exposure. Yet both groups gave about 2% X-linked lethals, the standard for measurement using a quantitative test that Muller had worked out for his 1927 paper. Untreated control flies gave 1 X-linked lethal per 2000 X chromosomes examined.

Muller and his student, G. Pontecorvo, also determined in 1940 that X-rays induced a condition called 'dominant lethals.' These appeared in abundance when Muller did his 1927 work inducing mutations with X-rays. At high doses (about 4000 R) about 90% of the embryos or eggs laid by females receiving the X-rayed sperm did not hatch larvae. Muller and Pontecorvo designed stocks to reveal that the cause was a chromosomal rearrangement in which chromosomes lacked or contained two centromeres. The centromere is the attachment region of a chromosome when it is pulled to the cell's poles during cell division. Independently, Barbara McClintock found the same phenomenon in maize and she called it a 'breakage-fusion-bridge cycle.' Muller argued after the reports of radiation sickness from the atomic bombings in Japan, that the breakage-fusion-bridge cycle caused the cells to die and since a person in Hiroshima or Nagasaki would have massive chromosome breaks the vulnerable tissues were those that had actively dividing cells such as skin, intestinal lining, bone marrow for red blood cell formation, lining cells of the blood vessels, reproductive tissue, and cells of the immune system. This resulted in the rashes, bleeding through the intestines, drop in blood count, diminished immunity to infections, peritonitis, and other damage reflected in the survivors of radiation sickness.

The concerns over radiation increased as the Cold War developed and the USSR began testing its own atomic weapons, including hydrogen bombs. These released large amounts of radioactive material that were carried in the atmosphere and dropped in rain called 'fallout.' When the United States tested its early hydrogen bombs in the Pacific, a boat with Japanese fishermen many miles away from the test were showered with radioactive fallout that made them sick with the same symptoms as radiation sickness. The United States quickly learned how to detect small doses of radiation (atmospheric fallout) from Soviet tests and a debate erupted over the safety to the civilian population in the United States from these atomic bomb tests. There were three positions that evolved. Edward Teller and Willard Libby took the position that small doses of radiation were harmless or beneficial. In Teller's view the fallout increased the number of mutations, which made evolutionary change possible. Some geneticists cited by the Atomic Energy Commission took the view that heterozygosity induced by radiation was good for a person because it induced hybrid vigor.

Opposed to this view were those who advocated an immediate halt to weapons testing because small doses of radiation were harmful. Chief advocate for this second view was Linus Pauling. He estimated the number of new genetic deaths and health effects of radiation fallout world-wide and they numbered several tens of thousands. Pauling admitted this was a small rise above control rates but felt it was immoral to cause any deaths when weapons testing treaties could prevent them and even unilateral stopping of tests would put pressure on the USSR not to do atmospheric tests. Muller represented a third view. He argued that low doses produced small amounts of damage but one had to balance national security (deterring the USSR from using nuclear weapons) against these sacrifices. He felt it was false to exaggerate low dose effects by either denying their existence or exaggerating their significance to health. He opposed unilateral stopping of nuclear tests and favored bilateral discussions. The debate was never resolved by scientific consensus. Instead, Pauling's efforts to get political action worked and the United States and the USSR worked out a treaty to ban atmospheric testing. No such testing by either power has occurred since.

Muller's Views on the World View of Science

Muller rejected the supernatural in any aspect of science. He fought against those who wished to substitute religious creationism for the origin of life, diversity, and species formation on earth. He was a reductionist who believed science could take any aspect of the natural world, reduce it to its components and show how these work and how the coordinated system functions. He rejected vitalism, holism, and other philosophies of science that invoked some supernatural component (élan vital, enteleche, soul, spirit, or essence). But Muller also believed in ideals to live by. He felt we need them for our careers, our families, and our participation in social life as citizens. He believed human values had an evolutionary history, both cooperative and aggressive behavior being products of mammalian behavior and sometimes subject to endocrine regulation at times of stress or different stages of the life cycle. He believed we can favor and select behavior that fosters respect for differences, tolerance for divergent views, empathy for others, and qualities that we call leadership. It was those components of our personalities that he hoped to cultivate through positive eugenics. Yet even with a eugenic outlet denied by social fears of abuse, he felt this secular humanist outlook was one we should emulate. He became active in the American Humanist Association and served as their President and was named Humanist of the Year in 1957.

Muller lost his faith in communism through his experience in the USSR, even testifying to Congress during the height of the Cold War that he would rather be dead than live his life in a Stalinist society. He never abandoned his belief in the central tenets of democratic socialism such as that practiced in Scandinavia or by the Labor Party in Great Britain. He believed in

government provision of education, health, retirement, and welfare because there was no way a capitalist society could provide them through private charity or private insurance when the wages of laborers would be barely sufficient to provide transportation, food, clothing, and shelter.

Muller's Status after His Death in 1967

Classical genetics has been absorbed by molecular genetics. Muller's idea in 1936 of the gene as a type of crystal that reproduced its variations and which might someday be worked out through X-ray diffraction analysis came true almost 20 years later with the working out of the double helix model of DNA (Muller, 1936b). Muller's view of mutation as a change in the individual gene has been worked out at a molecular level with the type of lesions agents cause within the gene. These are described as changes in the nucleotides or as minute additions or losses or inversions of one or more nucleotides in DNA. The existence of modifier genes and chief genes as a method for generating variations in character expression has been found in many organisms. Muller played a role in getting his post-doctoral student, Charlotte Auerbach, at Edinburgh to perform the first experiments to demonstrate induction of mutations by chemicals. She used mustard gas and hundreds of compounds have been found since then that act as mutagens. Muller's name today is attached to a concept called Muller's ratchet and evolutionary theory is still debating how effective gene loss and chromosome size diminution is associated with this process. While historians of science continue to study Muller's life and career, his name has faded as did that of his own mentor, Thomas Hunt Morgan, and most of the founders of classical genetics between 1900 and 1930.

Muller's name resurfaces when controversies over radiation hazards arise or when discussions of the outcome of new mutations in humans arise. He has been attacked by some of those who favor expanded use of nuclear reactors for electric power and by those who disregard low-dose effects of radiation. Muller fought hard to protect the public in the 1950s by serving on national committees to regulate the emerging nuclear power industry. He argued that as low a dose as possible should be the standard for building and operating nuclear plants because if the initial standards were generous to industry it would be almost impossible to alter those facilities once they were in operation. He also succeeded in getting the health professions to regulate radiation exposure to both practitioners and the public. New technologies of digital X-ray imaging have greatly reduced doses for diagnostic X-rays.

Muller was small in size (about five foot two inches tall), athletic (he enjoyed hiking), well-informed about current events, and he carefully limited his interests to that of his family, national politics, the world of science, and the ideals he chose to live by. He had no hobbies. He rarely relaxed and he worked 7 days a week. He was generous to his students. He allowed them to publish in their own names. He was a demanding mentor who made his students write and rewrite their articles and dissertation until all the criticisms he could introduce were answered.

What is unusual in Muller's career is the amount of attention he applied to the uses and abuses of new scientific findings, especially from his own work. Many scientists adopt an 'ivory tower' role of doing basic science and not concerning themselves with the application of science to society. Muller had enormous personal courage. At a time when two of his Russian students were arrested and later executed during the Stalin Terror years of 1936–38, he took on Lysenko in public debate. He spoke out because he believed that biology necessarily will be at odds with state, commercial, and special interest views of sex, heredity, scientific method, and the integrity of new knowledge.

Muller's papers are chiefly to be found at the Lilly Library at Indiana University in Bloomington. A smaller concentration of papers, many of them his letters to his family, were donated by his son and daughter to the Cold Spring Harbor Laboratory Library archives. The author of this article also donated his Muller papers to the Cold Spring Harbor Laboratory Library archives. The author also wrote a biography of Muller. Muller is a major figure in James Schwarz's book, *In Pursuit of the Gene* (Schwartz, 2008).

Multicultural Education

James A Banks, University of Washington, Seattle, WA, USA

Abstract

Multicultural education emerged out of the Civil Rights Movement in the United States in which African-Americans demanded that educational and other institutions incorporate their history and culture into the curriculum and make other reforms that would create greater educational equality. The Civil Rights Movement echoed throughout the United States and the world and stimulated other marginalized groups to make similar demands of schools, colleges, and universities, as well as other institutions within their nation-states. This article describes the goals, scope, and implementation of multicultural education in the Western immigrant nations of the United States, Canada, and Australia; in several Western European nations; and in Japan, Korea, and China. It also explains how citizenship education is being conceptualized and implemented in a number of multicultural nations.

The Goals and Scope of Multicultural Education

Multicultural education is an educational reform movement whose major aim is to change schools, colleges, and universities so that students from diverse groups will experience equal educational opportunities. The specific groups that are the focus of multicultural educational reform differ both within and across nations. In the democratic Western nations that view themselves as immigrant nations such as Australia, Canada, and the United States, the groups that are the focus of multicultural education include racial, ethnic, cultural, social-class, linguistic, and religious groups. However, especially within the United States, groups with disabilities as well as students who are gifted and talented often receive attention within multicultural education school, college, and university programs. Since the late 1990s, LGBT (lesbian, gay, bisexual, and transgender) students have become a significant focus of multicultural education in the United States (Mayo, 2013).

Multicultural education first developed in the United States in response to the African American Civil Rights Movement that occurred during the late 1960s and 1970s. African-Americans demanded that schools, colleges, and universities include content about their history and culture in the curriculum and hire African-American teachers, professors, and administrators. Other ethnic groups within the United States, such as Mexican Americans, Asian Americans, and American Indians, made demands similar to those made by African-Americans. Consequently, ethnic studies was the first focus of multicultural education in the United States.

The quests by African-Americans to achieve equal rights in education and within other areas – such as affirmative action in employment and cultural representation in museums and historical sites – echoed throughout the world. Indigenous and ethnic groups in other nations also demanded structural inclusion and educational equality. They called for schools, colleges, and universities to incorporate their cultures and histories into the curriculum and to hire teachers and professors from their racial, ethnic, cultural, and language groups. African Caribbeans in the United Kingdom, First Nations people in Canada, the Australian Aborigines, and the Maori in New Zealand pushed for the inclusion of their histories and cultures into the school, college, and university curriculum. During the late 1990s and 2000s, these groups also asked educational institutions to make teaching in schools more culturally responsive to the unique cultures of the students from their ethnic, cultural, and language communities (Banks, 2009; de Haan, 2012).

Multicultural Education in Western Europe

Many nations in Western Europe – such as France, The Netherlands, Switzerland, Ireland, and England – are facing challenges providing equal educational opportunities for groups that are marginalized because of their racial, ethnic, cultural, linguistic, and religious characteristics. These groups are also challenging notions of citizenship and citizenship education in European nations and forcing a reexamination of these concepts. Schools, colleges, and universities in many European nations have implemented a variety of initiatives and programs to increase the academic achievement of ethnic, linguistic, and religious minority students and to facilitate their participation in mainstream culture and institutions (de Haan, 2012; Osler and Starkey, 2009; Starkey, 2012; Tomlinson, 2009).

When the Civil Rights Movement began in the United States in the 1960s and 1970s, the Western European nations were characterized by ethnic, cultural, racial, linguistic, and religious diversity. Much of this diversity had deep historical roots. The nations in Western Europe had long-standing linguistic and cultural minorities, such as the Basques in France and Spain, the Germans in Denmark, the Danes in Germany, and the Welsh, Scots, and Jews in the United Kingdom. Diversity in European nations was greatly increased when thousands of immigrants from colonial nations came to Europe to improve their economic and social status and to meet labor needs in the years after World War II. These immigrant groups included Asian Indians, Pakistanis, and Jamaicans in England; the Vietnamese and North Africans in France; the Turks in Germany; and the Surinamese in the Netherlands. This series of migrations from former colonial nations was described in a book published in England by the Centre for Contemporary Cultural

Studies at the University of Birmingham in 1982 titled, *The Empire Strikes Back*: *Race and Racism in 70s Britain*.

There is a wide gap between the democratic ideals in European nations and the daily educational experiences of minority groups in schools (Tomlinson, 2004). Ethnic minority students in Europe, as in other nations throughout the world, often experience discrimination because of their cultural, linguistic, and religious differences. Both students and teachers often perceive these students as the 'Other.' When they are marginalized within school and treated as the 'Other,' ethnic minority students – such as Turkish students in Germany and Muslim students in France – tend to emphasize their ethnic identity and to have weak attachments to their nation-state (Mannitz, 2005; Tomlinson, 2009). The extent to which nation-states make multicultural citizenship possible, the recognition and visibility of diverse groups in the curriculum, and the linguistic rights of immigrant and minority groups are among the unresolved and contentious educational issues in European nations.

The academic achievement gap between ethnic minority and majority group students is another salient issue that is being theorized and researched by multicultural education scholars in Europe. African-Caribbean, Pakistani, and Bangladeshi students in Britain and Turkish students in Germany are not achieving on a level equal to that of majority group students in their nations. However, the underachievement of minority students is a complex issue worldwide that defies facile solutions and responses. Indian and Chinese students are the highest-achieving students in Britain (Tomlinson, 2004). In the United States, the academic achievement of Chinese, Japanese, and Asian Indian students exceeds the achievement of White students.

Multicultural Education in East Asian Nations

The construction and evolution of multicultural education in Asian nations such as Japan, Korea, and China has differed in significant ways from its development in the immigrant nations of Australia, Canada, and the United States as well in most European nations. Both Japan and Korea have historically viewed themselves as homogeneous nations with one dominant ethnic group, language, and culture. Little public recognition or attention has been given to the Ainu, the indigenous people of Japan. The Burakumin, which is often referred to as Japan's 'invisible race,' is another marginalized group that has historically experienced discrimination.

Japan and Korea have historically had a *jus sanguinis* notion of citizenship, whereby individuals needed Japanese or Korean 'blood' to become citizens (Hirasawa, 2009; Moon, 2012). This is in contrast to *jus soli*, which automatically grants citizenship to individuals born within a nation, which is the practice in the United States. In the past, citizenship in Germany was also based on the idea of *jus sanguinis*.

Multicultural education in Japan developed after a significant number of immigrants began to settle there in the 1990s (Hirasawa, 2009). In 2008, approximately 2.2 million people with non-Japanese nationality lived in Japan, which was about 1.74% of the population. Migration to Korea has increased significantly since the 2000s. Most of the immigrants to Korea are migrant workers, individuals from other nations who marry Koreans, and people who defect from North Korea (Moon, 2012). The 1 million migrants who were living in Korea in 2008 made up more than 2% of the national population.

China has 56 official ethnic groups, which consist of the dominant or mainstream Han people and 55 ethnic minority groups, which is approximately 123 million people and about 9.44% of the Chinese population (Teng and Zhu, 2012). Ethnic autonomous regions, which make up half of the geographical region of China, are the areas where most ethnic minorities in China live (Postiglione, 2009). The major goal of multicultural education in China is to enable ethnic minority groups to attain literacy in Mandarin Chinese and to acquire the other knowledge and skills needed to function in mainstream Han society without alienating these students from their home languages and cultures. Most ethnic minority students in China enter school speaking an indigenous language or languages and have little proficiency in Mandarin Chinese, which is the national language and the language needed for social mobility and structural inclusion.

The official policy in China is for ethnic minority students to retain their own language or languages while learning Mandarin Chinese. However, the strong assimilationist policy implemented in most schools in China results in many ethnic and linguistically minority students becoming alienated from their home and community cultures and languages (Beckett and Postiglione, 2012; Wang and Phillon, 2009). Important goals of citizenship education in China are for all students to develop an identity with the Chinese national political system and to internalize and respect collectivism (Wan, 2004).

Multicultural Citizenship Education

A significant goal of multicultural education in various nations is to help students from diverse racial, ethnic, cultural, linguistic, and religious groups to attain the citizenship knowledge and skills needed to function effectively within their own cultural communities, across other cultures and communities, within their nation-state, and within the global community (Banks, 2008). This goal is a serious challenge for nations around the world – there is a wide gap in both democratic nations and socialist nations between the ideals that are articulated about diversity and inclusion and the realities within classrooms and schools. Wide gaps between national ideals and actual practices in schools, colleges, and universities exist within the Western democratic nations such as the United States and the United Kingdom as well as in socialist nations such as the People's Republic of China (Wan, 2004) and the Republic of Cuba (Carnoy, 2009). Banks (2004) calls the gap between ideals and practices a 'citizenship education' dilemma.

Multicultural nation-states are faced with the problem of constructing a national culture and identity that reflects and incorporates the diversity of its citizens and yet have an overarching set of shared values, ideals, and goals to which all of its citizens are committed. Citizenship education theorists such as Banks (2007), Gutmann (2004), and Klymlicka (1995) assert that only when a nation-state is unified by inclusive values such as justice and equality can it protect the rights of cultural,

ethnic, religious, and linguistic groups and enable them to experience cultural democracy and freedom. Klymlicka (1995), the Canadian political theorist, and Rosaldo (1997), the US anthropologist, have constructed theories about diversity and citizenship. Both Kymlicka and Rosaldo state that in a democratic society, ethnic and immigrant groups should have the right to maintain their ethnic cultures and languages as well as participate fully in the national civic culture. Kymlicka calls this concept 'multicultural citizenship'; Rosaldo refers to it as 'cultural citizenship.'

In the United States in the 1920s Drachsler (1920) used *cultural democracy* to describe what citizenship education theorists call multicultural citizenship today. Drachsler (1920) and Kallen (1924) – who were Jewish immigrants and advocates for the cultural freedom and rights of the Southern, Central, and East European immigrants in the United States – argued that *cultural democracy* is an important characteristic of a democratic society. They maintained that cultural democracy should coexist with political and economic democracy, and that citizens from diverse groups in a democratic society should participate freely in the civic life of the nation-state and experience economic equality. They should also have the right to maintain important aspects of their community cultures and languages, as long as they do not conflict with the shared democratic ideals of the nation-state. Cultural democracy, argued Drachsler, is an essential component of a political democracy.

Balancing Unity and Diversity

Cultural, ethnic, racial, linguistic, and religious diversity exists in most nations around the world (Banks, 2009). One of the challenges to diverse democratic nation-states is to provide opportunities for different groups to maintain aspects of their community cultures while constructing a nation in which these groups are structurally included and to which they feel allegiance. Citizenship education theorists such as Banks and his colleagues (2005) believe that a delicate balance of diversity and unity is an essential goal of democratic nations and of teaching and learning in democratic societies and that unity should be an important aim when nation-states are responding to diversity within their populations. Gutmann (2004) states that nation-states can protect the rights of minorities and enable diverse groups to participate only when they are unified around a set of democratic values such as justice and equality.

In the past, most nations have tried to create unity by forcing racial, cultural, ethnic, linguistic, and religious minorities to give up their community languages and cultures in order to participate in the national civic culture (Joshee, 2009; Nieto, 2009; Tomlinson, 2009). During the 1950s and 1960s in the Southwest of the United States, Mexican-American students were sometimes punished for speaking Spanish in school. In the nineteenth century in the United States, American-Indian youth were forced to attend boarding schools where their cultures and languages were eradicated (Lomawaima and McCarty, 2006). In Australia, Aboriginal children were taken from their families and forced to live on state missions and reserves (Broome, 1982), a practice that lasted from 1869 to 1969. These children are called 'The stolen generation.' Kevin Rudd, the Australian Prime Minister, issued a formal apology to the stolen generation on 13 February 2008.

Citizenship education theorists believe that in order to embrace the national civic culture, students from diverse groups must feel that it reflects their experiences, hopes, and dreams and that schools and nations cannot marginalize the cultures of groups and expect them to feel structurally included within the nation and to develop a strong allegiance to it.

Multicultural Education across Nations

The major goal of multicultural education is to reform schools, colleges, and universities so that students from diverse groups will experience cultural recognition, educational equality, and structural inclusion. However, multicultural education reflects the national, cultural, and social context of the nation in which it is implemented. Not only do the groups on which multicultural education focuses vary by the national and social context, its approaches, implementation, and assessment are also influenced by contextual and nationwide factors. As the implementation of multicultural cross cultures and nations, it is transformed and mediated. However, its aim of increasing equality and social justice is consistent when it is implemented in different cultures and nations.

Multiculturalism

Abstract

Multiculturalism refers to (1) the state of a society or the world in which there exists numerous distinct ethnic and cultural groups seen to be politically relevant; and (2) a program or policy promoting such a society. Political philosophers aspire to deal with the challenges posed by multiculturalism fairly – but there is deep disagreement about what constitutes fair treatment. Multiculturalism might entail the granting of rights (individual or collective) on the grounds of the value cultures have for individuals, or even society as a whole. A multicultural state then might be one in which different forms of recognition are granted to cultural groups to secure the valuable goods cultural membership provides equally and avoid unfairly privileging dominant groups. On the other hand, it can be argued that precisely because of deep social and cultural diversity, the state should remain neutral between groups and ensure that basic liberal rights are fairly and consistently applied across cultural differences. Granting recognition to groups risks undermining the security and welfare of individuals by 'politicizing' forms of cultural identification best kept out of public decision making about the distribution of goods and resources. These views reflect not only conflicting intuitions about the relation between culture and individual welfare, but also deep disagreements about the nature of equality and freedom.

Multiculturalism has come to refer to (1) the state of a society or the world in which there exists numerous distinct ethnic and cultural groups seen to be politically relevant; and (2) a program or policy advocating or promoting such a society. The first is a factual claim, the second evaluative. But like so many claims in the social sciences, the empirical claim involves much more than empirical judgments, and the evaluative claim is contested by as many who promote it (and certainly does not follow from the empirical claim). Controversy has raged over what the best response to the fact of cultural diversity in the world might be, and it is not too much to suggest that the social and political issues raised by multiculturalism continue to be among the most pressing and important of our time. In recent years, multiculturalism also has come under increasing attack from commentators on both the left and the right. Coming to grips with these issues requires asking some difficult questions about the nature of culture and its relation to human welfare, and especially what political consequences follow in light of the answers given. Political philosophers aspire to deal with the challenges posed by multiculturalism *fairly*; the problem is, no one is quite sure what this actually entails.

The Relevance of Culture

Human societies have always been culturally diverse and certainly most organized political societies. Yet for much of the history of Western political philosophy, the ideals of political life that have been promulgated have presumed that citizens shared not only a common political status but also a common descent, language, and culture. Aristotle, for example, one of the central figures in the history of Western political thought, presumed this despite himself being a 'resident alien' of Athens. John Stuart Mill, champion of modern liberty and individual autonomy, thought that free institutions were next to 'impossible' among a people 'without fellow feelings,' or who read and spoke different languages. He argued that the boundaries of a state should coincide "in the main with those of nationalities" (Mill, 1975: p. 392). The presumption that states should be culturally homogeneous was inspired in part, no doubt, by straightforward prejudice against foreigners and outsiders, but it also was linked to a series of issues that continue to bedevil contemporary political philosophers. Among these include the following: Does justice require a common culture to motivate the goodwill and sacrifices it typically demands of citizens? Can a political society be stable if too much emphasis is placed on the diversity of its peoples and cultures? Can democratic institutions work, and be seen to be legitimate, if the citizens of a state speak different languages, have different worldviews, and even perceive the history of their nation differently? Finally, if individuals are fundamentally equal, can we balance the demands of equality with the diverse moral commitments of particular cultures?

Political philosophers from Aristotle to Mill (and beyond) have tended to answer these questions in the negative; too much cultural diversity threatens to undermine the possibilities for a peaceful, prosperous, and ultimately just political community. The problem is, the challenges of cultural diversity are impossible to avoid. The history of the twentieth century, and especially of recent decades, makes this abundantly clear; witness the reemergence of nationalism, the spread of violent ethnic conflict, and the extraordinary movement of peoples across borders fleeing persecution of various kinds and seeking new hope in distant lands.

Before tackling these questions directly, however, it is important to get a sense of what actually is meant by 'culture' and how it has come to occupy a preeminent position in discussions concerning distributive justice and the emergence of 'the politics of difference.'

Diversity of What?

Theorists concerned with multiculturalism agree that culture matters, but they disagree profoundly over how and why it does. Liberal political philosophers, in particular, have struggled to reconcile their commitment to the welfare of

individuals with what seems to be the collective nature of cultural identification. But first, when political philosophers talk about cultural diversity, what are they are actually talking *about*?

The concept of 'culture' has a complex history and, as a result, a set of meanings sometimes at odds with each other (Moody-Adams, 1997; Appiah, 2005). At a basic level, culture refers to the particular set of habits, beliefs, and customary practices of a people or society; to its way of life. In the nineteenth century, culture often was tied closely with quasi-biological notions of race and ethnicity, and thus to judgments about the inherent superiority of one form of culture over another – a tendency that continued to manifest itself in murderous ways throughout the twentieth century. Linking culture to biological or quasi-scientific characteristics thus has come to been seen as extremely dubious, involving both bad science and questionable ethics. Instead, anthropologists (among others) have argued that culture should be understood as a set of ultimately malleable and negotiable cognitive and social frameworks governing human behavior that is complex and dynamic rather than static and that is patched together from a variety of sources rather than woven of the same cloth (Geertz, 1973; Clifford, 1988; Moody-Adams, 1997; Appiah, 2005).

But how are cultures individuated politically? Some insist that the groups that matter politically are those grounded in *ethnicity* (stripped of any biological or scientific overtones): a people united by certain prepolitical allegiances of ancestry, collective memory, homeland, or culture (Smith, 1986). For others, cultural diversity refers to a range of different groups – whether based on ethnicity, race, socioeconomic class, language, lifestyle, or sexual orientation – who are disadvantaged relative to a dominant political culture manifested in the main institutions and 'public reason' of the state in which they reside (Young, 1990). Those shared characteristics or practices, often only perceived as being shared in light of 'mainstream' oppression or rejection, are said (for better or worse) to partly constitute the culture of a group.

Another important account of cultural diversity is provided by Will Kymlicka (1995a, 1998, cf 1995b, 2007). He argues that multiculturalism involves two different kinds of cultural diversity. The first is a diversity of 'societal cultures.' The second is created by individual and familial migration. A societal culture provides its members "with meaningful ways of life across the full range of human activities, including social, educational, religious, recreational, and economic life, encompassing both public and private spheres" (1995a: p. 76). It consists of not only collective values and memories, but usually also a shared language and territory (1995a: pp. 76–80). Note that these are *cultural* groups rather than groups based on race or descent. Membership thus is defined in terms of integration into a cultural community rather than in terms of descent. Aboriginal 'Nations' and the Quebecois, for example, are societal cultures, but also ones in which there is a high degree of racial and ethnic intermixing and thus great internal diversity. Although a state may contain a dominant societal culture, it also might include other minority cultures. Kymlicka called these groups 'national minorities': at the time of their incorporation into a larger state they possessed (1) a distinct 'social vocabulary' embodied in a full set of social practices and institutions, (2) were territorially distinct, and (3) self-governing. The capacity and motivation to form such a culture, for Kymlicka, means it is characteristic of 'nations' or 'peoples.' Migrants, on the other hand (and refugees, although they present a difficult case), essentially have chosen to give up their societal culture when deciding to migrate (1995a: pp. 100–101). So multiculturalism involves (at least) both 'polyethnic' diversity (arising from individual and familial migration) and 'multinational' diversity (arising from the incorporation of previously self-governing cultures into a larger state). Religious groups who seek out marginalization from mainstream society present something of a special case, which will be discussed later. Furthermore, there are groups which cut across ethnic and national lines – such as women, gays and lesbians, and the disabled – who, at different times, make claims based on their disadvantage or difference relative to a dominant societal culture. These claims tend to have more in common with 'polyethnic' rather than 'multinational' claims, however, since they usually concern the terms of integration into society rather than a demand for the preservation or protection of a distinct society (cf Kymlicka, 1998: pp. 90–103).

The reason why so much hangs on how a culture is to be individuated is because of what is said to follow in terms of the *rights* members of that culture – or indeed the group itself – can claim. For Kymlicka, 'national groups' are entitled to strong group rights; that is, those that entail varying degrees of self-government and protection from the decisions of the wider political community. Polyethnic rights are important but much weaker; they are concerned mainly with ensuring that the terms of integration into the dominant societal culture are as fair as possible.

Any set of distinctions generates anomalies and hard cases, and Kymlicka's is no different. Some groups, like certain religious groups, seem to fulfill the criteria for being a 'societal culture' and yet usually are not granted rights associated with national minorities. In some cases however, some 'ethno-religious' sects – such as the Amish or Hutterites in North America – have been granted exemptions from general laws to enable them to maintain certain key features of their religious life. But these are historically special cases; they usually involve a theology that seeks to minimize contact with the modern world. Other groups, such as refugees and some migrant groups (e.g., Muslim communities in the United Kingdom), do not fit comfortably into either category; they are not national minorities, but they also seem more vulnerable to collective harm than the discussion of 'polyethnic' rights might suggest. But how is it that rights follow from claims about culture in the first place?

Cultural Rights

What is striking about recent debates among liberals about multiculturalism is how liberalism's traditional concern with individual well-being has been linked to the value of cultural membership – an ostensibly 'collectivist' value. Not all cultures are individualistic, of course, but liberals generally are concerned with how culture matters for the lives of individuals. But how exactly does culture matter in this way? And even if it does, is it something in relation to which rights should be, or even could be, assigned?

Consider three basic arguments:

1. *The argument from cultural diversity*: Respect for cultural pluralism entails preserving existing cultures. Pluralism is valuable because it provides individuals with alternative ways to live, promotes critical reflection on the culture within which one currently lives, and thus promotes change and growth within cultures generally.
2. *The historical injustice argument*: Certain group rights are justified insofar as they are aimed at redressing or compensating for a history of past injustice against particular historical communities at the hands of dominant majorities.
3. *The value of cultural membership argument*: Certain group rights are justified insofar as membership in a culture has value for individuals, and there is a link between the welfare of the group and welfare of its members. Group rights contribute to the preservation of that culture and thus to the welfare of its members.

All three arguments have played a prominent role in recent debates. However, (1) seems incomplete, because the promotion of cultural diversity per se does not necessarily justify the protection of any *particular* culture. Furthermore, if more cultural diversity is better than less, then either all cultural practices are multiculturalism-enhancing and deserving of toleration or support, or only some are. The former cannot be true (as surely some cultural practices are not so deserving), and the latter forces us to identify those properties, which make some cultural practices valuable and others not. This is no easy task. This leads to consideration of (2) and (3). Perhaps the most powerful case has been one made in relation to (3). The historical injustice argument will be returned to in the Section The Future of Multiculturalism.

One way in which cultures matter to individuals is that they constitute an important aspect of their identity, or as Kymlicka put it, provide a meaningful 'context for choice': "freedom involves making choices amongst various options, and our societal culture not only provides these options, but also makes them meaningful to us" (1995a, 1995b). So in addition to the familiar liberal emphasis on individuals having the freedom of expression, movement, and association, they also need access to a societal culture. A societal culture is a basic 'primary good' for all individuals, and thus relevant to a liberal theory of justice (on primary goods, see Rawls, 1971).

A variation of this argument (but made independently of it) is the relation said to exist between cultural identity and individual self-respect or self-esteem. People's self-respect can be bound up with the way in which their group is perceived by others. Lack of esteem for the group can translate into lack of esteem on the part of individual members and this constitutes harm, the remedy of which may justify granting some form of group rights or rights of self-determination (Taylor et al., 1992; Margalit and Raz, 1990; on the 'social bases of self-respect' see Rawls, 1971: pp. 303, 440).

But do individuals require access to a *particular* culture to secure these benefits, one they can call their own? There are at least three objections to this strategy. Some argue that liberals should not be in the business of preserving particular cultures, since the kind of society they should be promoting is one in which individuals are free to move and adapt *between* cultures as much as within them. So as long as individuals have access to a societal culture – and especially one made up of a diversity of cross-cutting cultural influences – their 'context for choice' is secure. If there is a cultural structure that liberals should promote, it is a cosmopolitan one, a common but diverse 'mélange' of cultural meanings conditioned by the basic liberal freedoms of conscience, expression, association, and exit (Waldron, 1992; Turner, 1993; Appiah, 2005, 2007).

A variation on the cosmopolitan argument is to place greater emphasis on the value of diversity or difference itself. There is no identity without difference, and thus to talk of 'societal cultures,' or even a singular 'cosmopolitan culture,' is to risk missing the inherent multiplicity and hybridity of political and cultural identities. Individuals and groups are constituted by a diversity of moral sources, and the central task of justice should be to remain 'critically responsive' to this fluidity and diversity, rather than reinforce 'found' or extant cultural structures (Bhabha, 1994; Connolly, 1995).

Finally, granting special rights to cultural groups on the grounds of their value for individuals involves a delicate balancing act between the rights of individuals and the measures needed to ensure the survival of the culture. The dangers here are ones to which liberals should be especially sensitive. For some, even to talk about 'societal cultures' or groups as meriting political recognition is to engage in dubious metaphysics and unwise politics. The basic units of social reality cannot be group-based because groups are simply the product of interactions between individuals; there are only associations constituted by individuals and not vice versa (Kukathas, 1997). Thus, there are no grounds upon which to provide political or legal recognition for groups on the basis of their playing a 'constitutive' role in individuals' personal identity. Of course, individuals are free to associate with whom they please. But they are equally free to exit those associations. Moreover, empowering groups works against promoting the kind of social solidarity required for effective democratic societies – either by promoting divisive ethnic 'entrepreneurship,' or undermining a sense of common purpose required for comprehensive social programs (Barry, 2001).

The Politics of Multiculturalism

Disagreement over the social ontology of multiculturalism only intensifies when the more concrete matter of deriving political and institutional arrangements from them arises. The 'politics' of multiculturalism refers to the way in which the consequences of social and cultural diversity are thought to necessitate social and political change.

If the argument is that cultures matter to individuals because they are connected to the capacity for living a good life – whether in terms of providing the 'social bases of self-respect' or as a meaningful 'context for choice' – then does it follow that the *state* has a direct interest in recognizing or promoting a societal culture (or set of cultures)?

For cosmopolitans, it does not follow at all. People are sure to value their cultural attachments, but the state should steer clear of tampering with these commitments. It should treat them the way it treats religious beliefs, as a private matter about

which the state is officially neutral. If it promotes anything, it should be the ability of people to live according to whatever way of life they wish drawn from the many possibilities on offer, consistent with the basic rights of others to do likewise. So the state should remain 'indifferent' toward and generally tolerant of the associations individuals wish to form or join. The costs of a 'politics of difference' – of recognizing and encouraging individuals to organize politically around their cultural identities – outweigh any potential benefits. Politics can be a source of oppression as much as any other social practice, especially given the potential for cultural elites or others to gain control of the resources and institutions set up to protect cultural minorities and use them to take advantage of more vulnerable members or to enrich themselves (Kukathas, 1997: p. 149; Hardin, 1995; Barry, 2001). If individuals are being harmed as a result of their cultural attachments, then the remedy is to ensure a more consistent application of basic liberal rights and protections, not to recognize the groups to which they belong.

The latter view has been referred to as pursuing a policy of 'benign neglect' or 'neutrality.' Cultures neither deserve nor require state assistance to survive, and if they do, they probably are not worth preserving anyway. This view also has been associated with a 'civic' as opposed to 'ethnic' account of the state. A civic state is one in which citizens are members in virtue of a shared commitment to constitutional principles or values that are independent of particular cultural attachments (Habermas, 1993). An ethnic state, on the other hand, presupposes a set of values grounded in a shared cultural framework based on common descent or ethnicity. Hence, also the appeal to civic and ethnic nationalisms, the former involving 'constitutional' patriotism grounded in cosmopolitan principles independent of ethnocultural and historical features, and the latter entailing a particularist patriotism grounded in 'blood and soil.'

Practically speaking, however, the pursuit of neutrality or 'benign neglect' in these ways is extremely difficult to accomplish. States play a crucial role in coordinating social and economic activity, and it is inevitable that, in the process, certain cultural presumptions and practices will be favored over others. Almost every state, for example, has to establish internal boundaries, a common educational system, an 'official' language (or set of languages), and common holidays, and has to enforce a basic legal framework within which citizens will have to act. In other words, the idea that government could be neutral when it comes to the treatment of all cultural groups is not only difficult to imagine, but perhaps even 'incoherent' (Kymlicka, 1995a: p. 108). States have an inescapable cultural component built into them. Moreover, those states that often are invoked as exemplars of civic rather than ethnic nationalism or as having pursued a policy of 'benign neglect' have in fact possessed a distinct societal culture made up of more than just allegiance to cosmopolitan principles and values. Some groups have suffered harm as a result of their difference from this dominant societal culture. Some of these states have granted relatively strong group rights to various cultural groups in light of their disadvantage or via historic agreements in the course of nation building. (All of this seems true of the United States and Canada, for example, two apparently quintessential 'civic' nations.)

Focus on the *harm* people have suffered in relation to their particular cultural attachments has featured prominently in recent debates, mainly because of the appalling treatment just about every state has at some point handed out to minority groups. This touches on the historical injustice argument mentioned previously. Protecting societal cultures may be justified as a means of redressing or compensating members of that culture for a history of past discrimination or oppression at the hands of a dominant majority or minority (Buchanan, 1991; Spinner-Halev, 2012). There are questions surrounding this argument too, however. First, would citizens have to agree on a specific account of their nation's history to fix responsibility for these past injustices? This is difficult to imagine in many places in which intercultural conflict has been particularly brutal. Mutual loathing and distrust undermines cool and impartial reflection on the past.

Second, why should the viability of group rights depend on the group having been oppressed or discriminated against? Tying the granting of group rights to the existence of (past or present) discrimination by or exclusion from a dominant societal culture risks misunderstanding the motivation of groups seeking such rights.

Some societal cultures, it might be argued, are owed special rights independently of any historic pattern of disadvantage they may have suffered (as is argued is the case with Aboriginal peoples; see Kymlicka, 1995a: p. 142; Tully, 1995, 2008). Group rights, in other words, are not necessarily about compensation for exclusion from or discrimination by a dominant culture, but rather about the intrinsic commitment members of particular groups have toward their societal cultures.

But what kind of rights follow specifically in light of the arguments canvassed earlier? It is here that the generality of normative discussions about cultural rights runs up against the complexity of the world in which they are claimed; for it is difficult to imagine a generalizable set of rights that can be applied to all cultural groups equally, given the complex interplay of history, context, and principle in each case. The tensions inherent in the desire to protect both societal cultures and individual well-being emerge with particular force. The very measures needed to protect a societal culture might conflict with the actual freedoms and capacities of the individuals in whose name the protection is being offered in the first place (Hardin, 1995; Okin, 1998; Eisenberg and Spinner Halev, 2005). This is particularly true for those more vulnerable members of a societal culture, such as women and girls (Shachar, 2001; Song, 2007). Having suffered past injustice is no guarantee that relations *within* that group will be just. As a result, it is probably best to think of cultural rights as involving a bundle of different kinds of claims rather than as a complete set of universalizable principles, albeit always conditional on them not to harm the basic interests of individuals. Considered as such, they might include, among other things, the right to be exempted from certain laws or government policies; assistance for the maintenance of linguistic, educational, or cultural activities; various forms of recognition (legal, moral, and political); 'affirmative action' programs, representation rights, self-government rights (within a state or federation); and ultimately secession (Levy, 1997; on secession see Buchanan, 1991). Some of these claims involve negative rights of

noninterference, some positive rights of assistance, and others a combination of the two. Some might be compatible with individual rights (wieldable by individuals as members of that group) and some held exclusively by the group (wieldable by an agent or representative of that group). Much will depend on the context in which they are appealed to. Many inevitably will be controversial.

Aboriginal peoples, for example, have a strong claim for self-government rights because they hold land (or have strong claims to land), possess a distinct societal culture, were previously self-governing, and have suffered a long history of oppression and discrimination at the hands of most settler states. Despite the fact that some Aboriginal practices entail significant restrictions on individual liberty (e.g., rules governing property holding), most liberal theorists think the value and importance to Aboriginal people of maintaining their distinct cultural structure outweigh some of these concerns, or at least that fears of potential abuse are overstated (Kymlicka, 1995a; Tully, 1995; but cf Okin, 1998; Ivison, 2002). Needless to say, when concerning matters such as family law or criminal punishment, opinions begin to differ (Turpel, 1991; Okin, 1998; Pogge, 1997; Shachar, 2001). Self-government rights are the source of considerable debate and social division in countries where they have been claimed or granted. They present a significant challenge to traditional conceptions of equal citizenship and the principle of equality before the law.

Claims by religious groups, on the other hand, generally are not thought of in the same way. They might possess a distinctive societal culture, but save in exceptional circumstances they are not usually thought of as thereby possessing rights to a particular territory or self-government. Their claims more likely will have to do with exemptions from certain state laws, or for state support of education and cultural activities. But in states where religious groups do have extensive exemptions and privileges against the general population (e.g., as in Israel), even these 'weaker' claims can cause considerable social tensions (especially when combined with claims for self-government on the part of another historic community or societal culture living on the very same territory).

The Future of Multiculturalism

It often is suggested that the seemingly irreversible forces of globalization will result in the eventual eradication of the local or particular in favor of a global, although not necessarily cosmopolitan, Western, consumerist culture. Or, that with the end of the Cold War and the 'triumph' of liberal democracy, the great ideological battlelines of the past will be tamed and redrawn within a generally liberal framework (Fukayama, 1992). Recent developments in world politics, however, and especially ongoing ethnic tensions and conflict suggest otherwise. The local and particular has come back with a vengeance. Furthermore, within the established liberal democracies, many are questioning the programs established to promote multicultural identities, especially where they involve providing groups with extra resources or support to maintain their way of life, or as compensation for past discrimination and injustice. This is particularly evident in disputes surrounding the claims of Aboriginal peoples in Canada and Australasia, and reconsideration of 'affirmative action' programs and differentiated citizenship rights in the United States and Europe. The future of multiculturalism, in other words, might appear rather bleak.

Some have laid the blame for disenchantment with multiculturalist policies at the feet of those who were loudest in insisting on the 'recognition of difference' in the first place. Overemphasis on difference has encouraged (perhaps unwittingly) the reification of ethnic and cultural modes of identification, instead of taming them and making them more open-ended and dynamic (Turner, 1993; Hollinger, 1995; Barry, 2001). The constant demand for greater inclusiveness and plurality in every sphere of a nation's cultural life – from its school curricula and national history, to its political parties and assemblies – has sown the seeds of resentment and distrust rather than cross-cultural understanding (Schlessinger, 1991; cf the essays in Taylor et al., 1992; Connolly, 1995; Tully, 1995; Kymlicka, 1998, 2007). The constant focus on cultural, ethnic, and historical identities risks undermining, so it is argued, the necessary conditions for a stable and ultimately just political society, that is, a commitment to a common set of basic individual rights that are justifiable independently of any particular ethnocultural framework (Ignatieff, 1998; Barry, 2001).

Is the future multicultural? In many ways it must be, for the only way to rid societies and states of their diversity is to forcibly remove it, and that entails injustices of the worst kind (with which we are all too familiar). The case against multiculturalism as undermining political stability and the conditions for justice is weak, for it is clearly *not* the case that culturally homogeneous societies are the most just. It is also partly an empirical question, and the evidence so far suggests no strong correlation between multiculturalism and declining support for egalitarian policies (Banting and Kymlicka, 2006). Paradoxically, perhaps, the desire to respect difference and acknowledge alternative sources of moral commitment indeed may lead to the emergence of a kind of cosmopolitan culture 'multiculturalists' often are said to abhor. But if it does, this will not entail having moved 'beyond multiculturalism,' whatever that means. The common culture of justice is multicultural because the people to whom justice must be done and the societies within and between which it must be achieved are multicultural.

Abstract

Both a descriptive and a political term, migrating back and forth between politics, journalism, and academic research, multiculturalism cannot easily be defined. However, by common consent it refers simultaneously to ethnically and culturally complex societies and to policies recognizing difference with the aim to achieve equity between the constituent groups of such societies. The relationship between anthropology and multiculturalism is close, but fraught by tension and frictions, since the conceptualization of cultural identities and boundaries presupposed in multiculturalism both emanates from anthropology and has been superseded by theoretical developments in the discipline. Approaches to multiculturalism in anthropology range from studies of indigenous struggles and school curricula in North America to everyday cosmopolitanism in Malaysia and xenophobia in Europe. As an empirical phenomenon it clearly exists, although it is increasingly being challenged; as an analytical concept it is highly debatable.

Introduction

The extent to which historical and even prehistorical societies have been ethnically and culturally complex (and thus 'multicultural') has often been underestimated, but is now well known (Goodenough, 1976; Grillo, 1998). However, in the present context, the term multiculturalism is reserved for contemporary societies where discourses and policies relating to group-based cultural rights are pertinent. In the history of modernity, multiculturalism represents a departure from unilineal views of development, where persistent intrasocietal cultural diversity is acknowledged as a factor worth taking into account in politics.

Nevertheless, multiculturalism is not a simple term with a well-defined meaning. The *Oxford English Dictionary*, tracing its earliest appearance in English to an article about Switzerland published in 1957, defines it as "[t]he characteristics of a multicultural society; (also) the policy or process whereby the distinctive identities of the cultural groups within such a society are maintained or supported." This definition can be a useful starting point, and it notably distinguishes between descriptive and normative aspects of multiculturalism. However, as a matter of fact, very different 'multiculturalisms' are being promoted, which is a main reason why critiques of multiculturalism, usually misleadingly, tend to associate it with either an exaggerated relativistic tolerance of foreign customs and beliefs or an uncritical support of any kind of immigration into the country in question, where immigrants are accorded many rights and few duties. In a review of the term, Stuart Hall (2000) mentions no less than six multiculturalisms: conservative, liberal, pluralist, commercial, corporate, and critical or 'revolutionary' multiculturalism. Each has its approach to the central problem in culturally complex societies, namely, how to reconcile diversity with social solidarity. At the extreme ends of the spectrum are assimilationism (everybody who lives in the same country should have essentially the same culture) and difference multiculturalism (a kind not mentioned by Hall, see Turner, 1993), which demands that society should not be based on one set of values, but should accommodate, recognize the equality of, and indeed celebrate a great variety of cultural values. Vertovec (1998) also distinguishes between eight kinds of multiculturalism, while Delanty (2003) has proposed a list of nine varieties. In practice, most theories of multicultural societies and most state policies concerned with ethnic and cultural diversity try, in different ways, to strike a balance between the extremes of assimilation and segregation. On the one hand, too great a diversity makes solidarity and democratic participation difficult to achieve. On the other hand, total cultural homogeneity is an impossible (and, to most, undesirable) goal to achieve even in ethnically homogenous societies; in any complex society, there will exist religious sects and sexual minorities, to mention only two of the most obvious examples, demanding their right, if possible, to be 'equal but different.'

Seen as a set of policy principles or a political philosophy, multiculturalism is in other words not uniform but diverse, and it is shaped by the specific political, societal, and historical contexts in which it unfolds. One should thus, strictly speaking, talk of multiculturalisms in the plural, but for practical and didactical purposes, it appears reasonable to speak of it in an indefinite or definite singular sense, as the author has chosen to do in the present context. There is a widespread tendency in the literature on multiculturalism, both from its defenders and its opponents, to conflate distinctive social and cultural contexts, and not to distinguish properly between descriptive and prescriptive discourses. Yet, the idea that multiculturalism refers to a homogenous set of ideas and attitudes, is indefensible no matter.

History of Multiculturalism

Although multicultural societies are ancient, and cultural differences have been taken into account by rulers and political élites in many societies, multiculturalism as a coherent ideology is recent. As a tool of political governance, it was initially developed chiefly in Canada in the 1970s as a pragmatic response, influenced by both liberal and communitarian ideas, to rights claims from First Nations and burgeoning separatism among French-Canadians/Québecois, but it was soon applied

to contexts involving immigrants as well. Other countries that began to experiment with multiculturalist policies at an early stage were the United States, the United Kingdom, and Australia. As a rule, countries with considerable ethnic and cultural diversities have more easily adopted multiculturalist policies than others (Banting et al., 2006), since pluralism is part of their political architecture. The strengthening of multiculturalist ideology in many countries, particularly in the 1980s, must also be understood in the context of the rejection of dogmatic versions of Marxism on the political left, which entailed a widespread rejection of class as the main category for analysis as well as political action. A central element in this rejection was the refutation of the view that every form of oppression could be understood on the background of class, and that it would automatically cease to exist in the classless society envisioned by Marxists as the end of history. The new left, which developed from the 1970s, was concerned with a variety of forms of oppression, mobilizing on the basis of different kinds of 'politics of identity' linked to demands of equity and right claims among, for example, indigenous people, regional and immigrant ethnic minorities, women, and homosexuals. With the adoption of multiculturalism, the political left made what could be characterized as a 'cultural turn,' which has contributed strongly to the 'culturalization of politics,' which, according to the philosopher Slavoj Zizek, has marked the last decades (Zizek, 2008). As a consequence, Zizek argues, culture, including religion, has become an increasingly important framework for the understanding of contemporary political and societal development, at the expense of class. Kenan Malik, for his part, describes British multiculturalism as a process that emerged from, and was rooted in, the political and bureaucratic elites (Malik, 2009: p. 41), and Joppke and Lukes (1999: p. 2) claim that only in exceptional cases have oppressed minority persons themselves been the central actors – although one may probably object that the relationship between multiculturalism 'from above' and 'from below' has been shifting and complex in most countries. Canadian philosophers such as Will Kymlicka (1995) and Charles Taylor (1994 [1992]), who proposed intermediate positions or compromises between communitarian and liberal thought, were highly influential theorists in the refining of multiculturalist thought in the 1980s and 1990s.

By the early twenty-first century, departing from a situation where multiculturalism had a central, and in some cases decisive, part in the development of politics and law in the 1990s (Oomen, 2005: pp. 4–13), many countries reached a stage where multiculturalism increasingly was being placed under political pressure and subjected to criticism from various quarters, for contributing to the creation of 'parallel societies' and weakening the collective commitment to shared values and practices (Vertovec and Wessendorf, 2010). Joppke (2004) describes the situation as a total 'retreat' for multiculturalism as theory and policy in liberal states during the last decade. Banting et al. (2006: p. 5) also note that, the critique of and resistance toward multiculturalism formerly appeared to be the domain of the political and intellectual right, whereas it now increasingly appears on the political left, where there are deep concerns as to the effects of multiculturalist policies for socioeconomic equality, social cohesion, women's rights, and the welfare state in contemporary liberal and secular states.

Anthropology's Impact on Multiculturalism

'Multicultural' refers to the coexistence of 'several cultures' within a single society. The concept of culture presupposed in the composite term is the one developed in early to mid-twentieth century cultural anthropology, but with roots in German Romantic thinking, according to which cultures were seen as 'equal but different.' Ninteteenth-century anthropology had drawn upon an evolutionist concept of culture, enabling the ranking of cultures according to their achievements and level of development, whereas social and cultural anthropologists in the next century relied on cultural relativism as a methodological tool. According to this perspective, cultures cannot be ranked on an objective scale, since culturally neutral criteria for such an endeavor do not exist.

At the same time, the evolutionist and relativist perspectives on culture share the premise that human beings are fundamentally shaped by their cultures and that cultures are relatively uniform and bounded. Transposed onto a political canvas, such a conceptualization of culture may underpin nationalism (which it did in nineteenth-century Europe) or multiculturalism. In a context of group-based hierarchical domination, the same concept of culture may form the ideological justification for an ideology like apartheid, and as a matter of fact, anthropologists, notably Werner Eiselen at Stellenbosch University, were among the main intellectual architects of apartheid in South Africa.

The historical connection between the anthropological concept of culture and that of multiculturalist thinkers and policy makers has caused some friction, particularly during the period, since around 1980, when multiculturalism began to grow in significance as an ideological tendency in Western societies. At about the same time as it was being brought into widespread use in policy and politics, the classic concept of culture was increasingly being questioned and criticized within the discipline that made it, namely, anthropology. The criticism concerned the tendency of this concept to create the illusion of 'a global archipelago of cultures' – fixed, timeless, internally coherent – where there was in fact more ambiguity, process, fuzzy boundaries, and change. As a result, a refurbished, some would say poststructuralist, concept of culture (Clifford and Marcus, 1986 is the standard text) could now increasingly be used to criticize the simplifications and unwarranted reifications inherent in multiculturalist conceptualizations (Turner, 1993; Prato, 2009).

Anthropological Approaches to Multiculturalism

Anthropologists working in complex societies have increasingly been compelled to deal with questions pertaining to cultural rights and the politicization of diversity. Research on phenomena such as ethnic resource competition and civil war, cultural property rights, and general processes of exclusion and inclusion in complex societies, although pertaining to cultural diversity, are not considered here, since they are not directly relevant for multiculturalism narrowly defined as a kind of identity politics and/or ideology of governance aiming to achieve equity between culturally different groups without annihilating all cultural differences. This section, therefore,

considers the main areas of concern to anthropologists working on multiculturalist issues.

Postcolonial Societies

Research on multiculturalism has an obvious precursor in the conceptualization and study of plural societies. Originally coined by the geographer Furnivall (1948), the typical plural society was ruled by a colonial empire and peopled by diverse groups, some indigenous, some migrants. The quintessential plural society in the writings of Furnivall, Kuper, and Smith was a plantation society under colonial rule, or at least founded under colonial circumstances, such as could be found in British Burma, Malaya, Natal, Jamaica, or Mauritius (Kuper and Smith, 1969, see also Smith, 1965).

Societal cohesion in the plural society was contingent on external force (the colonial power); the constituent groups had few political rights, and the colonial rulers saw few benefits (for them) in encouraging the growth of a shared national culture. Encounters across ethnic boundaries were limited and largely took place in the market.

Criticized for reifying ethnic boundaries and underestimating the extent of contact across boundaries, the plural society approach nevertheless had its obvious merits in describing a particular kind of colonial society. With decolonization and new demands for broad political participation and citizenship, the coercive colonial ideology was often replaced with democratic slogans and political systems depending on a shared national identity. Attempts to reconcile the existing ethnic pluralism and the vestiges of the colonial, ethnic division of labor, on the one hand, with shared public culture and nationalism on the other, were carried out in many of the erstwhile plural societies, and have been analyzed by anthropologists (see, for example, Nagata, 1979; Eriksen, 1998). The degree to which former plural societies satisfy the criteria of multiculturalism nevertheless varies. To begin with, some are less plural than others; Jamaica is divided by class and color, but to a much lesser extent by ethnicity; Indonesia and Malaysia, although plural in character and multicultural in name, are numerically and politically dominated by one group (the Javanese and the Malay, respectively); Fiji is divided between an indigenous group and an immigrant one (Indians); and so on. However, it has been argued that the original plural colonial societies were precocious experiments in multiculturalism well ahead of the civil rights movements and postwar identity politics of the West. In Mauritius, for example, the French planters were granted cultural rights (to retain their language and religion) by their British conquerors as early as 1810.

Multiculturalism and the New World

There has been considerable anthropological interest in the multiculturalisms of New World countries such as the United States, Canada, and Australia, where questions pertaining to national and cultural identities have long been contested and ambiguous due to the immigration histories of these countries. As pointed out by Hutchinson (1994), major national celebrations of independence anniversaries in Canada (1968), the United States (1976), and Australia (1988) were derailed and subsequently redefined due to massive protests against the Eurocentric and simplistic representations of the national identity first proposed. The growth of cultural rights demands in these societies, dominated by white settlers for centuries, eventually led to calls, sometimes successful, for affirmative action, protective measures to safeguard indigenous cultures, and restructuring of school and university curricula along multiculturalist lines.

In these societies, anthropologists have engaged with the turn toward multiculturalism in interesting and sometimes innovative ways. Notably, for many, working on multiculturalism has represented a rare opportunity to practice engaged anthropology at home. Typically, anthropologists have found themselves in advocacy roles when working with indigenous groups/First Nations or ethnic minorities, but have often taken a more critical stance toward multiculturalist trends in the educational system. Although generally supportive of efforts to make curricula less Eurocentric (and androcentric), anthropologists have often taken exception to tendencies toward essentialization.

Although usually sympathetic toward multiculturalist ideology to the extent that it confirms the antiethnocentric bias inherent in anthropology, anthropologists have rarely defended radical multiculturalist projects involving, for example, polygyny. At least in the North American/Australian context, anthropologists have tended to side with 'critical multiculturalism' aiming to achieve equality for all groups in a multiethnic state, but more rarely with 'difference multiculturalism' (Turner's, 1993, concepts) where the ultimate goal is social, cultural, and moral separatism. It may be noted here that anthropologists in Brazil, a country with a comparable but in important respects different history, have moved in a different direction. Following the lead of Viveiros de Castro (1992) and others, contemporary Brazilian anthropology of cultural difference 'at home' tends to emphasize the continued existence of radical difference and speaks more of land rights than of reading lists.

Migrants in Europe

Owing to important historical differences, the anthropology of multiculturalism in Europe tends to have a different focus from that in the New World. Moreover, as correctly pointed out by Kymlicka (1995), the politics of identity among indigenous peoples is not simply replicated in immigrant groups, many of which represent very different interests from the indigenous movement. Demands for territorial and cultural autonomy have been crucial for most indigenous groups, whereas immigrants typically demand equal treatment and nondiscrimination. Within this ideological discourse, differential treatment (e.g., in the health service or educational system) should ultimately aim. However, especially since around 1990, many immigrant groups in the West, especially those of Muslim religion, have demanded recognition for their cultural specificities as well, and in some countries, issues to do with the language of instruction in schools are vigorously debated.

While it is generally acknowledged in the New World that those societies are historically immigrant societies, and that continued immigration – although it may be stemmed and

limited – will take place, European societies are deeply divided over issues to do with immigration and the integration of immigrants. In fact, much of the current anthropological research on multiculturalism in Europe has racism, discrimination, and xenophobia as its main focus (e.g., Holmes, 2000; Bowen, 2007), and in addition, the 'failed multiculturalism' of Yugoslavia and the subsequent horrors of 'ethnic cleansing' has its own, somber literature (Bringa, 1995; Bowman, 2004). Indeed, the emerging polarization in European societies around migration and ethnic diversity, punctuated by a scattering of terrorist attacks from both militant Islamists and right-wing xenophobes in the 2000s, has led several political leaders to denounce the term multiculturalism. This denunciation has itself spawned an academic literature, notably Lentin and Titley (2011) and Vertovec and Wessendorf (2010), which asks about the causes and effects of the 'crisis of multiculturalism.' While Lentin and Titley focus mainly on the rise of anti-immigrant sentiment, Vertovec and Wessendorf explore the semantics of multiculturalism and the relationship between political rhetoric and media talk on the one hand, and practices on the other. They conclude that most multiculturalist policies continue in spite of the pessimistic turn, but increasingly under the epithet 'diversity' rather than the largely discredited term 'multiculturalism.'

Multiculturalism and Globalization

A different approach to multiculturalism is offered by the literature on globalization. As pointed out repeatedly by anthropologists working in the field (Hannerz, 1996; Appadurai, 1996), globalization does not lead to uniformity, but to a reconfiguration of difference. The phenomenal growth in collective assertions of identity and claims to difference, which has been a worldwide trend since the latter decades of the twentieth century, must nevertheless be understood on the background of perceived challenges to cultural uniqueness and selfhood.

Assertions of cultural uniqueness as responses to encroaching homogenization may find expression in nationalism or collective withdrawal, but may also be expressed as celebrations of diversity and of 'rainbow societies' of various kinds. The latter kind of multiculturalism, with its focus on esthetic and commercial aspects rather than political ones, moreover has a ready market in the global tourism industry, where the demand for a sanitized and harmless 'cultural otherness' is on the rise (cf Comaroff and Comaroff, 2009).

As with the other forms of multiculturalism considered, the culture concept utilized here is reifying, limited, and selective. It presupposes an archipelago metaphor for the world of cultures – bounded, homogenous, and mostly unchanging – where a processual conceptualization emphasizing overlaps, change, and impurities would have been more descriptively appropriate. However, the standard anthropological response to this would not be to castigate multiculturalists of all kinds for using a dated and inadequate concept of culture, but to study how this static and reified culture concept is put to use – and how it gives existential meaning to people, is drawn into political struggles and converted into a marketable commodity.

The Challenge of Normativity

Much of the extant literature on multiculturalism, academic and nonacademic, has a clear normative slant. It is engaged in the sense of trying to make a political difference. Although this is also true of some of the anthropological contributions, explicit normativity is problematic from the perspective of methodological cultural relativism, where the noncommitted, neutral, comparative, and analytical gaze is privileged and seen as virtuous. As Turner points out in his seminal article about anthropology and multiculturalism:

> *Multiculturalism*, unlike anthropology, is primarily a movement for change. To the extent that it has developed a theoretical analysis, it is primarily a conceptual framework for challenging the cultural hegemony of the dominant ethnic group (or the dominant class constituted almost exclusively by that ethnic group) Ö by calling for equal recognition of the cultural expressions of nonhegemonic groups within the educational system. (Turner, 1993: p. 412)

Writing about the implementation of multicultural curricula at Florida State University in the early 1990s, the anthropologists Paredes and Pohl (1995) describe their experience of the university politics involved. While their narrative confirms Turner's general description, they add a dimension that is often missing from the literature on recognition and multiculturalism, namely, class and power. First of all, they point out that multiculturalism, as a political project, is not really about the pursuit of intercultural knowledge, but 'about the political empowerment of historically subordinate segments of our own society or, more precisely, their admission into the ranks of the elite' (Paredes and Pohl, 1995: p. 199, see also Gutmann, 1999). They later conclude that multiculturalism, as it is dealt with in the American academy, is an aspect of high culture, and has nothing to do with the totality of culture, and as such, it differs not only descriptively but also normatively from the project of anthropology, which entails taking all aspects of culture equally seriously to the extent that they are meaningful and important to the people in question.

While this delineation of multiculturalism is narrowly limited to certain discourses in North America, the general points about class and normativity have a broader relevance. And, as has been made clear, because of the misleading conceptualization of culture, many anthropologists who do have a normative commitment still have mixed feelings about the multiculturalist project. It has been described, with reference to multiculturalist state policies in Mauritius, as 'apartheid with a friendly face' (Eriksen, 1997) since a paradox of a multiculturalist ideology aiming to recognize all groups under the heading 'unity in diversity,' is the fact that persons who do not define themselves primarily as members of ethnic groups, have no legitimate place in society. Baumann (1999) addresses this and other 'riddles' of multiculturalism in a book that advocates, on the basis of long-term fieldwork in an ethnically complex suburb of London, a pragmatic solution whereby both nationalists, ethnicists and religious devotees can be recognized as equals. Baumann also addresses the question of the

'cultural hybrids' who do not fit easily into an ethnic or national category.

Conclusion: Beyond Multiculturalism

Especially in North America, but also elsewhere, the classic concept of culture has been used for what it was worth in domestic identity politics, leading in some cases to controversial policies of multiculturalism, where individuals were endowed with particular rights according to their ethnic membership. Critics point out that multiculturalism in some of its versions resemble apartheid and also that by positing a simple one-to-one relationship between ethnic identity and culture, it not only encourages a 'disuniting of America' (Schlesinger, 1998), but also contributes to reifying misleading notions of culture seen as homogeneity, like so many nationalisms writ small. It may seem that multiculturalism has grave shortcomings in two respects: it is descriptively inadequate and misleading; and normatively, it may be a recipe for divisive identity politics through its emphasis on group membership as the basis of identification.

In practice, the potential separatism and groupness implied in multiculturalism tends to be counterbalanced by individualism and overarching practices and ideas. Still, the conceptual and descriptive problems with multiculturalism have prompted anthropologists to refine their conceptual toolbox when describing ethnically complex societies.

One alternative concept, which is gaining currency in local administration and politics in some societies, is interculturalism (cf Asgarally, 2005 with reference to Mauritius). Instead of stressing boundaries, as multiculturalism does, this concept emphasizes connectedness and relatedness.

Another term is superdiversity. Noting that many cities across the world had become, in the early twenty-first century, diverse in new ways, Vertovec (2006) coined this term. His point was that mobility had made the ethnic maps of contemporary cities more unstable and volatile than previously; that temporary workers, students, tourists, asylum seekers, and various intermediate groups, plus the internal mobility within the cities, created a relatively unpatterned urban space that was less stable and regular than terms like 'pluralism' or 'multiculturalism' might imply.

Various conceptualizations of cultural hybridity and ambiguous identities are also posited against the implied essentialism of multiculturalism (Prato, 2009; Hesse, 2000), where impurities, mixing, and even individual idiosyncrasies are emphasized as opposed to the boundedness of the 'many cultures' of multiculturalism.

Finally, there may be sound arguments for replacing 'multiculturalism' with 'diversity.' The latter term is, of course, less specific than the former, but it may turn out to be both more adequate as a descriptive term and more versatile in political contexts, since it does not a priori assume that the social world consists primarily of named cultural groups, but avoids fixation and leaves the options open, to paraphrase Bauman (1996).

Abstract

Multidimensional scaling (MDS) is a set of data-analytic tools for deriving a graphical representation of objects in a multidimensional space based on proximity relations among them. By the graphical representation, we gain intuitive understanding of the regularity governing the relationships among the objects. In this article, we introduce the basic concept and models of MDS along with its essential ingredients such as distance models, proximity data, fitting criteria, dimensionality selection. To illustrate the use of MDS, three useful MDS procedures (simple MDS, individual differences MDS, and unfolding analysis) are presented with empirical examples.

The Basic Concept of MDS

The notion of proximity (e.g., similarity/dissimilarity) among objects plays an important role in human cognition and development. It is a fundamental principle by which people categorize, generalize, and classify objects (Takane et al., 2009). Multidimensional scaling (MDS) is a set of statistical techniques to derive a spatial map of objects based on a set of distancelike quantities among the objects. MDS represents objects as points in a multidimensional space in such a way that points corresponding to similar objects are located close together, while dissimilar objects are located far apart. The derived map from MDS facilitates our intuitive understanding of proximity relations among the objects by identifying meaningful directions or regions (object clusters) in the space.

To illustrate the use of MDS, let us take a look at similarity rating data among eight US cities presented in **Table 1**. The data were collected from 10 university students, who were asked to indicate the degree of similarity between each pair of cities using an 11-point rating scale; a larger value indicates more similar cities. All participants completed a questionnaire with 28 pairs drawn from the eight US cities. The eight cities were (1) Seattle, (2) New York, (3) Miami, (4) Chicago, (5) San Diego, (6) Atlanta, (7) New Orleans, and (8) Denver. PROXSCAL (Busing et al., 1997) implemented in Statistical Packages for Social Sciences (SPSS) was used to analyze the data, assuming that all participants have an identical object configuration. (this case is called simple MDS),

Figure 1 displays the derived two-dimensional configuration of the eight US cities. The figure shows that the eight cities are roughly classified into four groups, the first group consisting of Seattle and Denver, the second consisting of Chicago and New York, the third consisting of Atlanta and New Orleans, and the fourth consisting of San Diego and Miami. Dimension 1 (the horizontal direction) contrasts New Orleans, Atlanta, New York, and Chicago with Denver, San Diego, and Seattle. We may call the horizontal direction the east–west dimension from right to left. Dimension 2 (the vertical direction), on the other hand, separates Seattle, New York, Chicago, and Denver from New Orleans, Miami, San Diego, and Atlanta. We may call the vertical direction the north–south dimension from top to bottom. It is interesting to note that participants' perception of similarity among the cities seems to be, to a large extent, determined by their geographic locations. This may be because geographic locations are a truly important factor occupying participants' mind in judging similarity among the cities, or it may be because cities located geographically close have similar climate and culture (atmosphere, people's life style, etc.).

Distance Models

As illustrated above, MDS represents interobject similarities/dissimilarities by interpoint distances. The simple Euclidean distance model is most frequently used for this purpose due to its familiarity in our everyday life. This is also the model used to derive the configuration given in **Figure 1**. For other distance models such as the city-block distance model, see Carroll and Arabie (1998). The Euclidean distance between object points i and j (d_{ij}) is calculated by

$$d_{ij} = \left[\sum_{m=1}^{M} \left(x_{im} - x_{jm} \right)^2 \right]^{1/2}, \qquad [1]$$

where x_{im} and x_{jm} denote the coordinates of object points i and j on dimension m, respectively, and M indicates the dimensionality (the number of dimensions) of the space. Once the coordinates of object points are obtained (through MDS), we can locate the objects in the space using a Cartesian coordinate system. Note that the Euclidean distance is invariant over the choice of origin and orientation of coordinate axes. That is, the distance does not change if the origin of the space is shifted, or the coordinate axes are rotated. It is customary to place the origin at the centroid of the object configuration, and set the coordinate axes in the principal axis directions. In principal axis directions, dimension 1 accounts for the largest possible variance among object coordinates, dimension 2 accounts for the next largest variance, given that it is orthogonal to the first dimension, and so on. The principal axis directions are not necessarily most easily interpretable, and if necessary, they may be changed to other coordinate axes having easier interpretations. The configuration displayed in **Figure 1** was in fact rotated about 60° clockwise from the principal axis solution provided by PROXSCAL to facilitate interpretations.

Table 1 Similarity ratings among 8 US cities by 10 participants (1: very dissimilar, 11: very similar)

Participant	*1*	*2*	*3*	*4*	*5*	*6*	*7*	*Participant*	*1*	*2*	*3*	*4*	*5*	*6*	*7*
1	4							6	9

	1	2	6	2	2	3			3	2	4	5	4	6	
	8	1	1	2	1	2	1		4	3	2	5	4	6	6

The eight US cities are (1) Seattle, (2) New York, (3) Miami, (4) Chicago, (5) San Diego, (6) Atlanta, (7) New Orleans, and (8) Denver.

Figure 1 The two-dimensional object configuration of the eight US cities' data.

Proximity Data and Data Transformations

A variety of proximity data may be used in MDS, arising from a variety of data collection procedures, such as similarity ratings, sorting, same–different judgment, frequency of cooccurrences, reaction time, frequency of social interactions, and profile similarity. In similarity rating methods which are used to obtain the data in Table 1, objects are presented in a pair to the participants who are asked to rate the degree of similarity between them on a rating scale. In the sorting method, participants are given a set of objects and are asked to group them into several groups in terms of their similarity. The number of times two objects are put into same groups is counted over a group of participants and is used as a similarity measure between the objects. It is noteworthy that different proximity measures may reflect different aspects of proximity relations among objects, resulting in different configurations of the objects. For more systematic descriptions of the data collection methods and the related issues, see Takane et al. (2009).

Whichever data collection methods may be used, it is unlikely that observed proximity data can be directly

approximated by a distance model. The data may be similarity data (as in the data given in Table 1), which are inversely related to distances. In this case, the observed similarity data must be inversely monotonically transformed in order to be fitted by a distance model. Even if the data are dissimilarity data, they may not be linearly related to underlying distances, and need to be transformed before they can be fitted by a distance model. The problem of how the observed proximity data are related to the underlying distances is generally referred to as the scale level of measurement. Different scale levels require different types of transformations of proximity data.

Four scale levels are typically distinguished in MDS: ratio, interval, log-interval, and ordinal. These distinctions are important because certain MDS procedures are only appropriate for certain scale levels. MDS procedures assuming a ratio, interval, or log-interval scale are called metric MDS, while others assuming an ordinal scale are called nonmetric MDS (Shepard, 1962; Kruskal, 1964a,b). Let o_{ijk} denote the observed proximity between objects i and j for participant k. In the ratio scale, proximity data are assumed approximately related to distances (d_{ij}) by $a_k o_{ijk} \approx d_{ij}$, where a_k is positive (this is called a similarity transformation). In the interval-scaled measurement, it is assumed that $a_k o_{ijk} + b_k \approx d_{ij}$, where a_k is positive if the data are dissimilarity data, and negative if they are similarity data, and b_k is an arbitrary constant (this is called an affine transformation). In the log-interval scale, it is assumed that the observed proximity measures are related to underlying distances by a power transformation, $b_k o_{ijk}^{a_k} \approx d_{ij}$. If the log is taken on both sides, we obtain $a_k \ln o_{ijk} + \ln b_k \approx \ln d_{ij}$, which is a linear relationship between $\ln o_{ijk}$ and $\ln d_{ij}$, thus the name log-interval scale. In the ordinal scale level, o_{ijk} and d_{ij} are assumed to be only monotonically related. That is, $o_{ijk} > o_{i'j'k}$ implies $d_{ij} > d_{i'j'}$ if the data are dissimilarity data, whereas $o_{ijk} > o_{i'j'k}$ implies $d_{ij} < d_{i'j'}$ if the data are similarity data. In both cases, the transformation of the data can be expressed as $t_k(o_{ijk}) \approx d_{ij}$, where t_k is a monotonically increasing function if the data are dissimilarity, and it is a monotonically decreasing function if the data are similarity.

In empirical research, we usually do not know exact scale levels of the observed proximity data in advance. As a practical strategy, we may start with a less strict assumption (e.g., ordinal scale), and then may switch to a stronger assumption (e.g., interval–ratio scale) if appropriate. This may help avoid applying untenable scale level assumptions to the observed proximity data.

In the example given above, the data are similarity rating data. Analysis was carried out under the assumption that the data are ordinal (an inverse monotonic transformation) with the option that tied observations may be untied after the transformation.

Fitting Criteria

In practical data-analytic situations, an exact representation of the observed proximity data by a distance model is usually impossible due to measurement errors. MDS systematically searches for an object configuration and an optimal data transformation that minimizes the discrepancy between the transformed proximity data and the distance predictions. The discrepancy is quantified as a fit index (e.g., the normalized stress), which is also used as a fitting criterion to be minimized for estimating parameters in the model. Two broad classes of discrepancy functions have been used in MDS. One is the least squares (LS) criterion (Kruskal, 1964a,b), and the other is the maximum likelihood criterion (Ramsay, 1977, 1982). Although the maximum likelihood criterion has some appeals for its statistical inference capabilities with data with a large sample size, the LS criterion has been far more predominantly used in MDS for its simplicity and flexibility, requiring no rigid distributional assumptions. The LS criterion is stated as,

$$\varnothing = \sum_{k=1}^{K} \sum_{i<j} \left[t_k(o_{ijk}) - d_{ij} \right]^2, \qquad [2]$$

where t_k indicates a generic data transformation function, whose specific form depends on the scale level of proximity data, as described in the previous section. The LS MDS attempts to find the set of object coordinates x_{im} ($i = 1, \ldots, n$, where n is the number of objects and $m = 1, \ldots, M$), and data transformation parameters that minimize the discrepancy between the transformed proximity data $[t_k(o_{ijk})]$ and predicted distances (d_{ij}). Criterion [2] usually cannot be minimized in closed form, and some sort of iterative algorithms should be used (see Borg and Groenen (2005) for more details of the optimization algorithms used in MDS). The LS criterion used in MDS may have multiple local minima, and iterative optimization procedures may converge to one of them that is not the true minimum of the criterion we wish to find. This is called the local minima problem. To circumvent this difficulty, we may obtain multiple solutions with many different initial estimates and choose the best solution among them. In all results of MDS reported in this article, solutions were obtained with 100 random initial starts.

Dimensionality Selection

Dimensionality refers to the number of coordinates needed to locate objects in a multidimensional space. Two considerations should primarily be taken into account in determining the number of dimensions in MDS. First, the derived object configuration has to fit to the data at hand reasonably well. One practical strategy is to analyze the data under varied dimensionalities, say from 1 to 4, plot the fit value against the dimensionality (called a scree plot), and identify the point where the improvement in fit flattens out (called an elbow). Another important consideration is the interpretability of derived dimensions. We should retain only the meaningful dimensions that contribute to uncovering the underlying structure of proximity relations among objects.

In the example given above, the normalized raw stress values were 0.089 for the unidimensional solution, 0.034 for the two-dimensional solution, 0.013 for the three-dimensional solution, and 0.008 for the four-dimensional solution. The two-dimensional solution was considered optimal, where the improvement in fit flattened out.

Individual Differences MDS

As in the example given above, proximity data are typically collected from a number of participants. In the previous analysis, however, it was assumed that there were no systematic individual differences in the way the participants perceive similarities among the cities. This assumption may not be justified. There may be some interesting differences among the participants in their similarity judgments. Individual Differences MDS (ID MDS) was designed to capture both commonality and individual differences in similarity judgments (Carroll and Chang, 1970). ID MDS assumes that there is a common spatial representation of objects that applies to all individuals, while individual differences arise from differential weighting of common dimensions by different participants. It employs the weighted Euclidean distance model, which is written as,

$$d_{ijk} = \left[\sum_{m=1}^{M} w_{km} \left(x_{im} - x_{jm} \right)^2 \right]^{1/2}, \qquad [3]$$

where d_{ijk} is the distance between objects i and j for individual k, x_{im}, and x_{jm} are, as before, the coordinates of objects i and j on dimension m in the common object configuration, and w_{km} is the weight attached to dimension m by individual k. The d_{ij} in eqn [2] is replaced by d_{ijk} given above. Note that the model [3] reduces to the simple Euclidean distance model in eqn [1], if there is no individual differences in an object configuration, i.e., w_{km} is unity for all k and m. Using the weighted Euclidean distance model, ID MDS estimates both the common object coordinates (x_{im}) and the individual differences weights (w_{km}) in such a way that the predicted distance (d_{ijk}) best matches the optimally transformed proximity data. To eliminate the scale indeterminacy between the common object configuration and the individual differences weights, the former is typically constrained to satisfy $\sum_{i=1}^{n} \frac{x_{im}^2}{n} = 1$ for $m = 1, \ldots, M$ where n is the number of objects. One important characteristic of the weighted Euclidean distance model is that there is no rotational indeterminacy in contrast with the simple Euclidean model. This means that the derived dimensions have intrinsic meanings, and we should interpret them as they are.

For illustration, we applied ID MDS to the eight US Cities data discussed earlier. Again, PROXSCAL was used to analyze the similarity data, but the weighted Euclidean distance model was applied this time. The normalized raw stress also indicated that the two-dimensional solution is best (the normalized raw stress values were 0.089 for the unidimensional solution, 0.031 for the two-dimensional solution, 0.009 for the three-dimensional solution, 0.005 for the four-dimensional solution). The derived two-dimensional common configuration was very similar to the one presented in Figure 1, and thus we omitted the presentation of the common configuration obtained from ID MDS (the only remarkable difference is in the overall size of the configuration due to the normalization constraint discussed above). Recall that the horizontal axis (dimension one) contrasts the east and the west, while the vertical axis (dimension two) contrasts the north and the south. Figure 2 depicts the individual differences weights attached to the two dimensions by different individuals. Although there are overall no big individual differences in this example, three noticeable participants are identified by numbers, 1, 9, and 10. Participant 1 puts more emphasis on dimension 1 than dimension 2, whereas participant 9 puts slightly more emphasis on dimension 2 than dimension 1. Participant 1 is more sensitive to the east–west difference, while participant 9 is opposite. Participant 10 puts almost equal emphasis on both dimensions. As can be seen, the weights may show interesting patterns of individual differences, which in turn may be related to participants' backgrounds (e.g., age, gender). For more examples of interesting applications of the ID MDS, see Takane (2007).

Figure 2 The plot of individual differences weights attached to the two dimensions by the 10 participants.

Unfolding Analysis

Unfolding analysis is a variant of MDS used to analyze individual differences in preference judgments (Coombs, 1964). As an example of preference data, let us look at **Table 2**. A group of 23 participants were asked to rank order 6 different cars from the most preferred to the least preferred. The six cars used were Honda Civic, BMW 328 Sedan, Mercedes C-Class Sedan, Lincoln Navigator, Toyota Camry, and Jeep Grand Cherokee. Tied ranks were allowed by assigning the average of ranks to them. The data are actually antipreference data, where a smaller value indicates more preference.

In unfolding analysis, each participant is assumed to have an ideal object represented as an ideal point in the same space as actual objects are represented. The distances between the ideal point and the actual object points are assumed to be inversely related to the participant's preferences on the objects; more preferred objects are located closer to the participant's ideal points, while less preferred objects are located further apart from the ideal points. Let x_{im} denote the coordinate of object i on dimension m, and y_{km} the coordinate

Table 2 Preference ranking among 6 cars by 23 participants (1: the most preferred, 6: the least preferred)

Participant	*Honda Civic*	*BMW 328 Sedan*	*Mercedes C-Class Sedan*	*Lincoln Navigator*	*Toyota Camry*	*Jeep Grand Cherokee*
1	3	4	6	2	1	5
2	3	6	1	5	2	4
3	5	1	2	6	3	4
4	1	3	4	5	2	6
5	4	2	1	6	3	5
6	1	4	3	5	2	6
7	2	4	3	1	5	6
8	1	3	4	5	2	6
9	5	3	2	4	1	6
10	5	1	3	2	6	4
11	5	1	1	6	6	4
12	5	4	6	3	1	2
13	1	3	5	4	2	6
14	1	3	2	6	5	4
15	5	1	2	6	4	3
16	2	1	3	6	4	5
17	6	3	2	4	5	1
18	1	4	3	5	2	6
19	3	6	5	2	4	1
20	5	1	2	3	4	6
21	2	1	3	6	4	5
22	6	4	3	1	5	2
23	5	2	4	3	6	1

The six cars are Honda Civic, BMW 328 Sedan, Mercedes C-Class Sedan, Lincoln Navigator, Toyota Camry, and Jeep Grand Cherokee.

of individual k's ideal point on dimension m. The Euclidean distance between actual object i and individual k's ideal point is calculated by

$$d_{ik} = \left[\sum_{m=1}^{M} (x_{im} - y_{km})^2 \right]^{1/2}. \qquad [4]$$

The coordinates of the actual objects and ideal points are determined in such a way that the preference values of the objects for particular individual are a decreasing function of the distance between them. This implies that the observed antipreference data are interpreted as dissimilarity data between participants' ideal objects and actual objects. As a result, we obtain two coordinate matrices, one for actual object points, and the other for participants' ideal points. The two coordinate matrices are used to derive a joint plot by superposing actual objects and participants' ideal points in a joint multidimensional space.

The data in **Table 2** were analyzed by PREFSCAL (Busing et al., 2005) implemented in SPSS. An optimal solution was obtained with 100 random initial starts under the assumption of ordinal scale. The normalized stress indicated that the two-dimensional solution is optimal (the normalized stress values were 0.176 for the unidimensional solution, 0.043 for the two-dimensional solution, 0.004 for the three-dimensional solution). **Figure 3** presents the joint MDS configuration of the participants' ideal points and the six cars. The participants were identified by the integers from 1 to 23. Note that a car is located close to participants' ideal

Figure 3 The joint plot of object points and participants' ideal points for the preference data on six cars. The six cars are Honda Civic, BMW 328 Sedan, Mercedes C-Class Sedan, Lincoln Navigator, Toyota Camry, and Jeep Grand Cherokee.

points if it is preferred by the participants. For example, participants 4, 6, 8, and 18 are located close to Honda Civic because these participants preferred Honda Civic to any other cars, while participants 3, 5, 11, 15, and 20 are located close to BMW 328 Sedan and Mercedes C-Class Sedan, preferred to any other cars. **Figure 3** also shows that the six cars are roughly classified into three groups, the first one consisting of Toyota Camry and Honda Civic, the second consisting of BMW 328 Sedan and Mercedes C-Class Sedan, and the third consisting of Lincoln Navigator and Jeep Grand Cherokee. The within-group cars have much in common, compared to the between-group cars. For example, Toyota Camry and Honda Civic are much more similar than others in that they are economic cars produced by Japanese manufacturers. As illustrated, unfolding analysis can be a very useful technique in marketing and consumer behavior research in that it allows us to understand patterns of individual differences in preference judgments on commercial products. The characteristics of individual differences in preference judgments can be further investigated by relating to product features and participants' background information. This sort of analysis may help marketing analysts to develop practical marketing strategies such as brand and product positioning. For more examples of application of unfolding analysis, refer to Takane (2007).

A Summary and Software for MDS

MDS is a class of statistical tools to visualize the relationships among objects in a spatial map, based on proximity and/or preference measures on the objects of interest. In this article, we addressed essential ingredients of MDS, such as the distance model, proximity data, fitting criteria, and

dimensionality selection. We also examined three useful models of MDS and their applications (i.e., simple MDS, ID MDS, and unfolding analysis).

In behavioral and social science research, SPSS has predominantly been used to analyze the proximity and preference data due to its comprehensive data-analytic capabilities and user-friendly graphical interface. For ID MDS, ALSCAL (Takane et al., 1977) implemented in SPSS has widely been used. However, PROXSCAL (Busing et al., 1997), recently implemented in SPSS, is gradually taking over the role of ALSCAL with more flexible visualizing and data-analytic features such as graphing capabilities and multiple random starts. For unfolding analysis, PREFSCAL (Busing et al., 2005), also recently incorporated in SPSS, has primarily been used in empirical research owing to its remarkable feature to overcome the degeneracy problems (e.g., all object points collapsing into one) prevalent in unfolding analysis.

Abstract

Multidimensional scaling (MDS) is a method for the visualization of dissimilarities between pairs of objects. The representation of the objects is done in a low (usually two)-dimensional space by the distance between the pairs of points. In metric MDS the distances approximate the dissimilarities directly, and in nonmetric (ordinal) MDS the distances should match the rank order of the dissimilarities as well as possible. As distance measure, almost invariably the Euclidean distance is used. The fit is expressed by the Stress value. The interpretation of the MDS configuration is done in terms of the distances between the points.

Introduction

Multidimensional scaling (MDS) is a statistical method that optimally maps proximity data on pairs of objects (i.e., data expressing the similarity or the dissimilarity of pairs of objects) into distances between points in a multidimensional space (usually two or three dimensions). Sometimes, MDS is also used as a container term for all methods that provide a graphical representation of variables and/or objects in a scatter plot. This definition is very broad and contains a wide variety of methods such as correspondence analysis, principal component analysis, canonical correlation analysis, etc. We here limit ourselves to the narrow sense definition of mapping proximities into distances.

To introduce MDS in a research context, we use an example from value research where MDS has always played a cardinal role. Values are guiding principles in people's lives, basic goals a person strives for in many actions and situations. Schwartz (2012) and many others have found 10 universal basic values: power (PO), achievement, hedonism, stimulation, self-direction, universalism, benevolence, tradition (TR), conformity (CO), and security (SE). These values, moreover, always exhibit certain structural relations. For example, persons who attach high importance to achievement also tend to rate benevolence as not so important, and vice versa.

Consider a sample of 151 US adults (Borg and Bardi, in press) who completed the Portrait Values Questionnaire (PVQ, http://wiki.mgto.org/portrait_value_questionnaire_pvq), a questionnaire of 40 items assessing how persons rate the relative importance of the 10 universal values. Value researchers typically first intercorrelate the scores of these items and then subject the correlation matrix to a 'default' MDS. This MDS optimally represents the items as points in two-dimensional space such that the distances of the points are (inversely) ordered just as the correlations of the items. Hence, the closer two points in the MDS solution (Figure 1), the higher the correlation of the items that they represent. The 40 points are coded here in terms of the basic values that the respective items are measuring. For example, 'co1' is item #1 of the PVQ measuring conformity, and 'po2' is item #2 on power. To facilitate interpretation, additional lines were added that cut the space like a cake into wedgelike *regions*. They form a *circumplex*, a circle of regions emanating from a common origin. Each region contains only items of one particular type – except for a few small errors where points (e.g., co4 or tr1) fall into the respective neighboring region.

The MDS solution in Figure 1 is a rather precise representation of the data. MDS comes with a fit index called *Stress*. Simulations show that the Stress of our MDS solution is clearly better than the Stress of any MDS solution for 1000 random permutations of the data. Hence, the MDS solution in Figure 1 is *significant*. Moreover, the circumplex pattern that we see here has been *replicated* in hundreds of similar studies. So, this structure is *robust*.

Rather than scaling items, we may first aggregate the 40 items to yield importance scores for each of the 10 values, and then do an MDS on the 10×10 correlation matrix of these scores. Figure 2 shows that this results in a simple

Figure 1 Ordinal multidimensional scaling solution for the intercorrelations of 40 Portrait Values Questionnaire items measuring 10 universal values. PO, power; AC, achievement; HE, hedonism; ST, stimulation; SD, self-direction; UN, universalism; BE, benevolence; TR, tradition; CO, conformity; SE, security.

Figure 2 Ordinal multidimensional scaling solution for the intercorrelations of relative importance scores for 10 universal values. PO, power; AC, achievement; HE, hedonism; ST, stimulation; SD, self-direction; UN, universalism; BE, benevolence; TR, tradition; CO, conformity; SE, security.

pattern: The 10 values are all on an almost perfect circle, and their order replicates what has been found in many other studies. The MDS solution is also significant (based on permutation tests). Moreover, repeating the MDS with only 9 of the 10 values (*jackknifing*) leads to very similar configurations. Thus, this MDS solution is also *stable*.

We can go on and ask whether it is possible to force the 10 value points onto a *perfect* circle, so that the values are actually ordered on a *one-dimensional circular scale*. We can impose this theory-driven *external* constraint onto the MDS solution. This turns *exploratory* MDS into *confirmatory* MDS. In this case, it can be done easily using *spherical* MDS. We find that the perfect-circle constraint increases the Stress only insignificantly, and so we should – for reasons of simplicity and theoretical meaningfulness – accept this configuration as the 'final' MDS solution for these data.

Figure 2 also shows a more traditional interpretation in terms of two *dimensions*: self-enhancement versus self-transcendence, and openness to change versus conservation.

Formalizing MDS

In MDS, one deals with three mathematical objects: data that are (or have been converted into) dissimilarities δ_{ij} (for each object pair i and j), where larger values indicate larger dissimilarity; a configuration of n points in m-dimensional space, described by an $n \times m$ matrix $\mathbf{X}$ of coordinate values; and the distances computed on $\mathbf{X}$, written as $d_{ij}(\mathbf{X})$.

When doing MDS, the user has to make some choices. An important feature of MDS is that instead of fitting distances directly to the observed dissimilarities, often a transformation $\widehat{d}_{ij}$ of the observed dissimilarities δ_{ij} are fitted to the distances. The goal of MDS is then to find both $\widehat{d}_{ij}$'s and distances $d_{ij}(\mathbf{X})$'s such that they match as closely as possible. Therefore, one of the choices to be made is to assign a particular scale level to the observed dissimilarities δ_{ij} (ordinal, interval, or ratio). Picking the ratio level amounts to requesting that $\widehat{d}_{ij} = b \cdot \delta_{ij} \approx d_{ij}(\mathbf{X})$, where b is a substantively irrelevant overall positive scaling constant. In interval MDS, one wants $\widehat{d}_{ij} = a + b \cdot \delta_{ij} \approx d_{ij}(\mathbf{X})$, where a and b are chosen optimally as long as the resulting $\widehat{d}_{ij} \geq 0$. And in ordinal MDS, the $\widehat{d}_{ij}$ can be rescaled in *any* way as long as they have the same order as the dissimilarities δ_{ij} so that if $\delta_{ij} \leq \delta_{kl}$ then we must have $\widehat{d}_{ij} \leq \widehat{d}_{kl}$.

A second choice is picking a distance function between rows i and j of $\mathbf{X}$. This is almost always the Euclidean distance that is defined by

$$d_{ij}(\mathbf{X}) = \left(\sum_{s=1}^{m} (x_{is} - x_{js})^2 \right)^{1/2} \qquad [1]$$

and has the simple interpretation of the length of the straight line connecting points i and j.

The core of what MDS attempts to accomplish is expressed by the so-called *Raw Stress* loss function. Raw Stress is the sum of the squared errors of representing a dissimilarity of $\widehat{d}_{ij}$ by the corresponding distance $d_{ij}(\mathbf{X})$, that is,

$$\sigma^2_{\text{raw}}(\widehat{\mathbf{D}}, \mathbf{X}) = \sum_{i=2}^{n} \sum_{j=1}^{i-1} w_{ij} \left(\widehat{d}_{ij} - d_{ij}(\mathbf{X}) \right)^2 \qquad [2]$$

where w_{ij} are nonnegative fixed weights set by the user to weight the importance of error ij (e.g., to handle missing data by setting $w_{ij} = 0$ if δ_{ij} is missing and $w_{ij} = 1$ otherwise) and $\widehat{\mathbf{D}}$ is the matrix with elements $\widehat{d}_{ij}$ that are related to the dissimilarities by one of the specified transformations (e.g., ordinal, interval, or ratio). The loss function [2] formalizes the objective of MDS in terms of a mathematical optimization problem. MDS seeks to minimize Raw Stress by pursuing two objectives: (1) finding an optimal matrix of coordinates $\mathbf{X}$ for given $\widehat{d}_{ij}$'s and (2) finding $\widehat{d}_{ij}$ values within the specified transformation for given distances $d_{ij}(\mathbf{X})$. However, minimization of $\sigma^2_{\text{raw}}(\widehat{\mathbf{D}}, \mathbf{X})$ over $\widehat{\mathbf{D}}$ and $\mathbf{X}$ would yield the trivial solution $\widehat{\mathbf{D}} = 0$ and $\mathbf{X} = 0$ (except when $\widehat{d}_{ij} = \delta_{ij}$). One way to steer away from this trivial solution is to replace $\sigma^2_{\text{raw}}(\widehat{\mathbf{D}}, \mathbf{X})$ by $\sigma^2_{\text{norm}}(\widehat{\mathbf{D}}, \mathbf{X})$ that imposes the explicit normalization restriction $\sum_{i>j} w_{ij} \widehat{d}^2_{ij} = 1$. Alternatively, implicit normalization could be used as in Stress-1 defined by
